

PRIOR AUTHORIZATION POLICY

POLICY: Adrenal Hyperplasia – Crenessity Prior Authorization Policy

- Crenessity™ (crinecerfont capsules and oral solution – Neurocrine Biosciences)

REVIEW DATE: 12/18/2024

OVERVIEW

Crenessity, a corticotropin-releasing factor type 1 receptor antagonist, is indicated for the treatment of classic congenital adrenal hyperplasia (CAH) as adjunctive treatment to glucocorticoid replacement to control androgens in adults and pediatric patients ≥ 4 years of age.¹

Disease Overview

Classic CAH due to 21-hydroxylase deficiency is the most common cause of primary adrenal insufficiency in children.² The prevalence of classic CAH is 1 in 10,000 to 1 in 15,000 live births. However, the prevalence of classic CAH is lower in Black and Asian populations. CAH typically presents during the newborn screening or by presentation of atypical genitalia in females. Early detection can prevent salt wasting adrenal crisis and decrease neonatal mortality. A diagnosis of CAH is most often confirmed during the newborn screenings which tests for elevated 17-hydroxyprogesterone levels. Other tests that are used in the diagnosis of CAH include cosyntropin stimulation tests and genetic testing with confirmed cytochrome (CYP)21A2 genotype. Management of classic CAH requires adequate glucocorticoid replacement with hydrocortisone at supraphysiological doses.

Clinical Efficacy

The efficacy of Crenessity for the treatment of classic CAH has been evaluated in two pivotal studies.^{1,3,4} One study included pediatric patients and the other included adults. Both studies required the patients to have a confirmed diagnosis of CAH and to receive a stable dose of glucocorticoid of $> 12 \text{ mg/m}^2/\text{day}$ in hydrocortisone dose equivalents. In both studies, compared with placebo, Crenessity significantly decreased serum androstenedione levels from baseline at Week 4. In addition, compared with placebo, the total glucocorticoid dose while androstenedione was controlled ($\leq 120\%$ of baseline or $\leq$ upper limit of normal) was significantly reduced in the Crenessity group at Week 24.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Crenessity. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Crenessity as well as the monitoring required for adverse events and long-term efficacy, initial approval requires Crenessity to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Crenessity is recommended in those who meet the following criteria:

12/18/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

FDA-Approved Indication

1. **Classic Congenital Adrenal Hyperplasia (CAH).** Approve for the duration noted if the patient meets ONE of the following (A and B):

A) Initial Therapy. Approve for 6 months if the patient meets ALL of the following (i, ii, and iii):

i. Patient is ≥ 4 years of age; AND

ii. Patient meets BOTH of the following (a and b):

a) The medication will be taken in combination with a systemic glucocorticoid; AND

Note: Examples of glucocorticoids include hydrocortisone, prednisone, prednisolone, or dexamethasone.

b) Patient has a diagnosis of 21-hydroxylase deficiency CAH confirmed by ONE of the following [(1), (2), (3), or (4)]:

(1) Elevated 17-hydroxyprogesterone level; OR

(2) Confirmed cytochrome (CYP)21A2 genotype; OR

(3) Positive newborn screening with confirmatory second-tier testing; OR

(4) Diagnostic results after cosyntropin stimulation; AND

iii. The medication is prescribed by or in consultation with an endocrinologist, urologist, or a physician who specializes in the treatment of adrenal hyperplasia.

B) Patient is Currently Receiving Crenessity. Approve for 1 year if, according to the prescriber, the patient is continuing to derive benefit from Crenessity.

Note: Examples of responses to Crenessity therapy are reduced androstenedione levels, decreased 17-hydroxyprogesterone levels, or reduction in glucocorticoid dose from baseline (i.e., prior to Crenessity therapy) or improved or stabilized clinical signs/symptoms of classic Congenital Adrenal Hyperplasia (e.g., decrease in body mass index standard deviation scores, improved insulin resistance, reduction of hirsutism, or improvement in androstenedione-to-testosterone ratio).

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Crenessity is not recommended in the following situations:

1. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

- POLICY:** Allergen Immunotherapy – Grass Pollen Sublingual Products Prior Authorization Policy
- Grastek® (Timothy grass pollen allergen extract sublingual tablets – ALK-Abello)
 - Oralair® (Sweet Vernal, Orchard, Perennial Rye, Timothy, and Kentucky Blue Grass mixed pollens allergen extract sublingual tablets – Stallergenes/Greer)

REVIEW DATE: 10/09/2024

OVERVIEW

Grastek and Oralair are grass pollen allergen extracts indicated for **allergic rhinitis**, with or without conjunctivitis, that has been confirmed by a positive skin test or *in vitro* test for pollen-specific immunoglobulin E (IgE) antibodies for Timothy grass or cross reactive grass pollens (Grastek) or any of the five grasses contained in the product (Oralair).^{1,2} These products are indicated in patients 5 through 65 years of age.

Per product labeling, Grastek must be initiated 12 weeks before the expected onset of each grass pollen season and Oralair must be initiated 4 months before the expected onset of each grass pollen season.^{1,2} Both agents must be continued throughout the season.

Clinical Efficacy

Pivotal trials of Grastek and Oralair included patients with grass pollen-induced allergic rhinitis with or without conjunctivitis confirmed by either a positive skin prick test to Timothy grass pollen or positive *in vitro* test.^{1,2}

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Grastek and Oralair. All approvals are provided for the duration noted below.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Grastek and Oralair is recommended in those who meet the following criteria:

FDA-Approved Indication

- 1. Grass Pollen-Induced Allergic Rhinitis.** Approve for 1 year if the patient meets ALL of the following (A, B and C):
 - A)** Patient is ≥ 5 years of age; AND
 - B)** The timing of prescribing meets ONE of the following (i or ii):
 - i.** Grastek: Therapy is initiated 12 weeks prior to the expected onset of the grass pollen season or therapy is being dosed daily continuously for consecutive grass pollen seasons; OR
 - ii.** Oralair: Therapy is initiated 4 months prior to the expected onset of the grass pollen season; AND
 - C)** The diagnosis of grass pollen-induced allergic rhinitis is confirmed by meeting ONE of the following (i or ii):

10/09/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- i. Patient has a positive skin test response to a grass pollen from the Pooideae subfamily of grasses (this includes, but is not limited to: sweet vernal, Kentucky blue grass, Timothy grass, orchard, or perennial rye grass); OR
- ii. Patient has a positive *in vitro* test (i.e., a blood test) for allergen-specific immunoglobulin E antibodies for a grass in the Pooideae subfamily of grasses (see examples above).

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Grastek and Oralair is not recommended in the following situations:

1. **Concurrent Use of Grastek or Oralair with Subcutaneous Allergen Immunotherapy or Sublingual Allergen Immunotherapy.** Note: This includes allergy shots as well as Odactra® [house dust mite {*Dermatophagoides farina* and *Dermatophagoides pteronyssinus*} allergen extract sublingual tablets], Ragwitek® [short ragweed pollen allergen extract sublingual tablets]). The efficacy of Grastek and Oralair has not been evaluated in patients who are receiving concomitant allergen immunotherapy.¹ Approved product labeling for both Grastek and Oralair states that concomitant dosing with other allergen immunotherapy may increase the risk of local or systemic adverse events to either subcutaneous or sublingual allergen immunotherapy.
2. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Allergen Immunotherapy – Odactra Prior Authorization Policy

- Odactra® (house dust mite [*Dermatophagoides farina* and *Dermatophagoides pteronyssinus*] allergen extract sublingual tablets – Merck)

REVIEW DATE: 10/09/2024

OVERVIEW

Odactra, a house dust mite allergen extract, is indicated as immunotherapy for **house dust mite-induced allergic rhinitis**, with or without conjunctivitis, confirmed by positive *in vitro* testing for immunoglobulin E (IgE) antibodies to house dust mites or skin testing to licensed house dust mite allergen extracts.¹ It is approved for use in patients 12 to 65 years of age. Odactra is not indicated for the immediate relief of allergic symptoms.

Clinical Efficacy

Pivotal trials of Odactra involved patients as young as 12 years of age with house dust mite-induced allergic rhinitis with or without conjunctivitis.²⁻⁴ The house dust mite sensitivity was confirmed by a positive skin test response to *Dermatophagoides pteronyssinus* and/or *D. farina* and a specific IgE level of ≥ 0.7 kU/L against *D. pteronyssinus*, *D. farina* or both.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Odactra. All approvals are provided for the duration noted below.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Odactra is recommended in those who meet the following criteria:

FDA-Approved Indication

2. **House Dust Mite-Induced Allergic Rhinitis.** Approve for 1 year if the patient meets BOTH of the following (A and B):
 - D) Patient is ≥ 12 years of age; AND
 - E) The diagnosis of house dust mite-induced allergic rhinitis is confirmed by meeting ONE of the following (i or ii):
 - i. Patient has a positive skin test response to house dust mite allergen extracts; OR
 - ii. Patient has a positive *in vitro* test (i.e., a blood test for allergen-specific immunoglobulin E antibodies) for house dust mite.

PRIOR AUTHORIZATION POLICY

POLICY: Allergen Immunotherapy – Palforzia Prior Authorization Policy

- Palforzia® (peanut [*Arachis hypogaea*] allergen powder-dnfp for oral administration – Aimmune)

REVIEW DATE: 03/20/2024; selected revision 04/24/2024 and 08/28/2024

OVERVIEW

Palforzia, an oral immunotherapy, is indicated for the mitigation of **allergic reactions**, including anaphylaxis, that may occur with accidental exposure to peanut.¹ It is approved for use in patients with a confirmed diagnosis of peanut allergy. Initial dose escalation may be administered to patients 1 through 17 years of age; up-dosing and maintenance may be continued in patients ≥ 1 year of age. Palforzia is labeled to be used in conjunction with a peanut-avoidant diet. It is not indicated for the emergency treatment of allergic reactions, including anaphylaxis. Prior to initiation, the prescriber should verify that the patient has injectable epinephrine and has been instructed on its appropriate use. Palforzia is contraindicated in patients with uncontrolled asthma and patients with a history of eosinophilic esophagitis and other eosinophilic gastrointestinal disease.

Clinical Efficacy

The Palforzia pivotal study in patients 4 to 17 years of age, PALISADE, included patients who were required to have a diagnosis of peanut allergy supported by either a serum peanut-specific immunoglobulin E (IgE) level of ≥ 0.35 allergen-specific unit per liter (kU_A/L) or a mean wheal diameter of at least 3 mm larger than the negative control to a skin prick test for peanut.² Additionally, to be eligible for randomization, patients had to have an allergic reaction (with dose-limiting symptoms) to a prespecified dose of peanut protein during a double-blind, placebo-controlled food challenge at screening. One of the key safety studies supporting the approval of Palforzia in patients 4 to 17 years of age used slightly different enrollment criteria.¹ Patients were required to have peanut allergy characterized by allergic signs and symptoms observed within 2 hours of known oral peanut exposure, along with a serum peanut-specific IgE ≥ 14 kU_A/L and a mean wheal diameter on skin prick test at least 8 mm larger than the negative control.¹ In the Palforzia pivotal study in patients 1 to 3 years of age, patients were required to have peanut allergy confirmed by a peanut-specific IgE test and a skin prick test.⁴

Guidelines

Current guidelines regarding diagnosis and management of food allergy state that parent and patient reports of food allergy must be confirmed.³ A skin prick test and allergen-specific IgE testing are each recommended as a method to identify foods that provoke allergic reactions. However, each test alone cannot be considered to be diagnostic for food allergy.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Palforzia. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Palforzia as well as the monitoring required for adverse events and long-term efficacy, approval requires Palforzia to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Palforzia is recommended in those who meet the following criteria:

FDA-Approved Indication

- 3. Peanut Allergy.** Approve for 1 year if the patient meets ALL of the following (A, B, C, D, E, and F):
- F)** Patient meets ONE of the following (i or ii):
- i.** Patient is 1 to 17 years of age; OR
 - ii.** Patient is ≥ 18 years of age AND has been previously started on therapy with Palforzia prior to becoming 18 years of age; AND
- G)** According to the prescriber, the patient has a of an allergic reaction to peanut that met ALL of the following (i, ii, and iii):
- i.** Patient demonstrated signs and symptoms of a significant systemic allergic reaction; AND
Note: Signs and symptoms of a significant systemic allergic reaction include hives, swelling, wheezing, hypotension, and gastrointestinal symptoms.
 - ii.** This reaction occurred within a short period of time following a known ingestion of peanut or peanut-containing food; AND
 - iii.** The prescriber deemed this reaction significant enough to require a prescription for an epinephrine auto-injector; AND
Note: Examples of epinephrine auto-injectors include EpiPen, EpiPen Jr., Auvi-Q, and generic epinephrine auto-injectors.
- H)** Patient meets ONE of the following (i or ii):
- i.** Patient meets BOTH of the following (1 and 2):
 - a) Patient has a positive skin prick test response to peanut with a wheal diameter ≥ 3 mm larger than the negative control; AND
 - b) Patient has a positive *in vitro* test (i.e., a blood test) for peanut-specific immunoglobulin E (IgE) with a level ≥ 0.35 kU_A/L; OR
 - ii.** Patient meets ONE of the following (1 or 2):
 - a) Patient has a positive skin prick test response to peanut with a wheal diameter ≥ 8 mm larger than the negative control; OR
 - b) Patient has a positive *in vitro* test (i.e., a blood test) for peanut-specific IgE with a level ≥ 14 kU_A/L; AND
- I)** According to the prescriber, Palforzia will be used in conjunction with a peanut-avoidant diet; AND
- J)** Patient does NOT have uncontrolled asthma; AND
- K)** The medication is prescribed by or in consultation with an allergist or immunologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Palforzia is not recommended in the following situations:

- 5.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Allergen Immunotherapy – Ragwitek Prior Authorization Policy

- Ragwitek® (short ragweed pollen allergen extract sublingual tablets – ALK-Abello)

REVIEW DATE: 10/09/2024

OVERVIEW

Ragwitek, a ragweed pollen allergen extract, is indicated as immunotherapy for the treatment of patients 5 to 65 years of age with **short ragweed pollen-induced allergic rhinitis** with or without conjunctivitis confirmed by a positive skin test or *in vitro* test for pollen-specific immunoglobulin E (IgE) antibodies for short ragweed pollen.¹ Ragwitek is not indicated for the immediate relief of allergy symptoms. Ragwitek is dosed once daily and must be initiated at least 12 weeks before the expected onset of ragweed pollen season and continued throughout the season.

Clinical Efficacy

Clinical trials of Ragwitek enrolled adults and pediatric patients with allergic rhinitis with or without conjunctivitis. Patients had their diagnosis confirmed by a positive skin prick test and positive *in vitro* testing for serum IgE antibodies for short ragweed.¹⁻⁴

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Ragwitek. All approvals are provided for the duration noted below.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Ragwitek is recommended in those who meet the following criteria:

FDA-Approved Indication

- 4. Short Ragweed Pollen-Induced Allergic Rhinitis.** Approve for 1 year if the patient meets ALL of the following (A, B, and C):
 - L)** Patient is ≥ 5 years of age; AND
 - M)** Ragwitek therapy is initiated 12 weeks prior to the expected onset of the short ragweed pollen season; AND
 - N)** The diagnosis of short ragweed pollen-induced allergic rhinitis is confirmed by meeting ONE of the following (i or ii):
 - i.** Patient has a positive skin test response to short ragweed pollen; OR
 - ii.** Patient has a positive *in vitro* test (i.e., a blood test) for allergen-specific immunoglobulin E antibodies for short ragweed pollen.

10/09/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Ragwitek is not recommended in the following situations:

6. **Concurrent Use of Ragwitek with Subcutaneous Allergen Immunotherapy or Sublingual Allergen Immunotherapy.** Note: This includes allergy shots as well as Grastek (Timothy grass pollen allergen extract sublingual tablets), Oralair (Sweet Vernal, Orchard, Perennial Rye, Timothy, and Kentucky Blue Grass mixed pollens allergen extract sublingual tablets), Odactra (house dust mite *{Dermatophagoides farina and Dermatophagoides pteronyssinus}* allergen extract sublingual tablets). The efficacy of Ragwitek has not been evaluated in patients who are receiving concomitant allergen immunotherapy.¹ Approved product labeling for Ragwitek states that concomitant dosing with other allergen immunotherapy may increase the risk of local or systemic adverse events to either subcutaneous or sublingual allergen immunotherapy.
7. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

- POLICY:** Alpha₁-Proteinase Inhibitor Products Prior Authorization Policy
- Aralast NP[®] (alpha₁-proteinase inhibitor [human] intravenous infusion – Shire)
 - Glassia[®] (alpha₁-proteinase inhibitor [human] intravenous infusion – Shire)
 - Prolastin[®]-C and Prolastin[®]-C Liquid (alpha₁-proteinase inhibitor [human] intravenous infusion – Grifols Therapeutics)
 - Zemaira[®] (alpha₁-proteinase inhibitor [human] intravenous infusion – CSL Behring)

REVIEW DATE: 12/11/2024

OVERVIEW

Alpha₁-proteinase inhibitor (also known as alpha₁-antitrypsin [AAT]), is indicated for **alpha₁-proteinase deficiency** as a chronic augmentation and maintenance therapy in adults with clinical evidence of emphysema.¹⁻⁵ The following products are available commercially in the US: Prolastin-C (also available as Prolastin-C Liquid), Aralast NP, Zemaira, and Glassia. The products vary in their availability and in some of their purification and viral inactivation processes.

Disease Overview

AAT deficiency is a rare, chronic, hereditary, autosomal co-dominant disorder marked by low concentrations of AAT which leads to progressive, severe emphysema that often does not manifest until the third to fourth decades of life.¹ Diagnosis of AAT deficiency begins with quantitative measurement of AAT levels in the plasma.⁶ A serum AAT level below 80 mg/dL (11 micromol/L) is considered suggestive of AAT deficiency. Treatment is aimed at raising serum levels of AAT above a theoretical protective threshold of 11 mM (mcmol/L), which is equivalent to the tenth percentile of the AAT range of PI*SZ individuals; epidemiological data suggest lower probability of chronic obstructive pulmonary disease (COPD) above this level.⁷ A variety of techniques have been used to measure serum AAT concentration.⁸ The most commonly used technique today is nephelometry. Using this technique, a serum AAT concentration < 57 mg/dL is usually associated with AAT deficiency with lung disease. Of note, older laboratory techniques (e.g., radial immunodiffusion) measured non-purified levels of AAT, which tend to overestimate the concentration by 35% to 40%.⁹ An AAT level of 80 mg/dL measured by radial immunodiffusion corresponds to a plasma AAT level of 11 mM.

Guidelines

A European Respiratory Society (ERS) statement addresses diagnosis and treatment of pulmonary disease in AAT deficiency (2017).⁶ It is noted that augmentation therapy has been shown to reduce progression of emphysema in severe AAT deficiency. There is no evidence to support efficacy of AAT augmentation therapy for current smokers of any phenotype. These guidelines support earlier American Thoracic Society (ATS)/ERS guidelines (2003) which state that intravenous augmentation therapy is recommended for individuals with established airflow obstruction from AAT deficiency.¹⁰

The Medical and Scientific Advisory Committee of the Alpha-1 Foundation guidelines (2016) provide similar recommendations.¹¹ Intravenous AAT augmentation is strongly recommended in non-smoking or ex-smoking patients with forced expiratory volume (FEV₁) 30 to 65% of predicted due to well-documented benefit in this group. Weaker recommendations also support treatment of patients with FEV₁ below 30% of predicted or above 65% of predicted. Usual management of COPD should also be provided, with strong emphasis on facilitating tobacco cessation. Of note, AAT replacement therapy is not recommended for patients who continue to smoke.

12/11/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Other Uses with Supportive Evidence

In the ATS/ERS 2003 guidelines, it is stated that AAT replacement therapy is a reasonable option for AAT deficiency-associated panniculitis.¹⁰ Although no controlled trials provide a clear treatment recommendation, augmentation therapy with purified human alpha₁-proteinase inhibitor or fresh frozen plasma to restore plasma and local tissue levels of AAT appears to be rational, safe, and effective. In a review of treatment options for panniculitis in AAT deficiency, augmentation therapy with alpha₁-proteinase inhibitor was noted to be the most successful medical treatment.¹²

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of alpha₁-proteinase inhibitor. All approvals are provided for the duration noted below.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of alpha₁-proteinase inhibitor (e.g., Aralast NP, Glassia, Prolastin-C, Prolastin-C Liquid, Zemaira) is recommended in those who meet one of the following criteria:

FDA-Approved Indication

1. Alpha₁-Antitrypsin Deficiency with Emphysema (or Chronic Obstructive Pulmonary Disease).

Approve for 1 year if the patient meets ALL of the following (A, B, and C):

A) Patient is ≥ 18 years of age; AND

B) Patient has a baseline (pretreatment) alpha₁-antitrypsin serum concentration of < 11 mcM (11 mmol/L) [< 80 mg/dL if measured by radial immunodiffusion or < 57 mg/dL if measured by nephelometry]; AND

C) According to the prescriber, the patient is a current non-smoker.

Other Uses with Supportive Evidence

2. Alpha₁-Antitrypsin Deficiency-Associated Panniculitis. Approve for 1 year if the patient is ≥ 18 years of age.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of alpha1-proteinase inhibitor is not recommended in the following situations:

- 1. Alpha₁-Antitrypsin Deficiency without Lung Disease, even if Deficiency-Induced Hepatic Disease is Present.** The ATS/ERS standards for the diagnosis and management of individuals with AAT deficiency (2003) state that the pathophysiology of liver disease in AAT deficiency is different from that of lung disease, and the use of alpha₁-proteinase inhibitor is not discussed for these patients.¹⁰ There is an absence of information that suggests alpha₁-proteinase inhibitor is useful in patients with AAT deficiency-related liver disease.
- 2. Bronchiectasis (without alpha₁-antitrypsin deficiency).** Studies have not demonstrated alpha₁ proteinase inhibitor to be effective for this condition. The ATS/ERS standards for the diagnosis and management of individuals with AAT deficiency (2003) state that despite the well-recognized association between AAT deficiency and the early development of emphysema, only a limited number of studies have assessed the association between AAT deficiency and bronchiectasis.¹⁰ Studies suggest that bronchiectasis is more a result of emphysematous changes in the parenchyma than of AAT deficiency.
- 3. Chronic Obstructive Pulmonary Disease (COPD) without Alpha₁-Antitrypsin Deficiency.** The Global Initiative for Chronic Obstructive Lung Disease guidelines for the diagnosis, management, and prevention of COPD (updated 2024) state that never or ex-smokers with an FEV₁ of 35 to 60% of predicted may be most suitable for AAT deficiency augmentation therapy; newer evidence suggests that individuals with higher FEV₁ values may also be candidates.¹³ However, this therapy is not recommended for COPD that is unrelated to AAT deficiency.
- 4.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

- POLICY:** Amifampridine Products Prior Authorization Policy
- Firdapse® (amifampridine tablets – Catalyst)
 - Ruzurgi® (amifampridine tablets – Jacobus [approval withdrawn])

REVIEW DATE: 07/31/2024

OVERVIEW

Amifampridine, a broad spectrum potassium channel blocker, is indicated for the **treatment of Lambert-Eaton myasthenic syndrome (LEMS)**.^{1,2}

- Firdapse is indicated in **adults and pediatric patients ≥ 6 years of age**.¹
- Ruzurgi was indicated in **patients 6 years to < 17 years of age** (prior to withdrawal of FDA approval).²

As of February 01, 2022, the FDA has withdrawn approval for Ruzurgi. Firdapse was approved by the FDA on November 28, 2018, for the treatment of LEMS in adults, with 7 years of orphan-drug exclusivity (ODE). On May 6, 2019, Ruzurgi was approved by the FDA for the treatment of LEMS in patients 6 to < 17 years of age. On June 12, 2019, Catalyst (manufacturer of Firdapse) brought suit against the FDA, challenging the FDA's approval of Ruzurgi stating that it violated the ODE for Firdapse. In 2022, the Court of Appeals for the Eleventh Circuit sided with Catalyst; therefore, the FDA had to withdraw approval for Ruzurgi. Due to the 7-year ODE for Firdapse, Ruzurgi may not be approved for marketing until ODE has expired on November 28, 2025.

Disease Overview

LEMS is a rare autoimmune disorder affecting the connection between nerves and muscles and causing proximal muscle weakness, autonomic dysfunction, and areflexia.^{3,4} The characteristic weakness is thought to be caused by antibodies generated against the P/Q-type voltage-gated calcium channels present on presynaptic nerve terminals and by diminished release of acetylcholine.⁴ The diagnosis of LEMS is confirmed by electrodiagnostic studies, including repetitive nerve stimulation, or anti-P/Q-type voltage-gated calcium channels antibody testing.

Clinical Efficacy

Firdapse was approved based on two pivotal trials.^{1,5} One pivotal trial enrolled both amifampridine-naïve and treatment-experienced patients; patients were initially entered into an open-label run-in phase lasting 90 days.⁵ During the open-label run-in phase, Firdapse was titrated for each individual patient to a dose that produced optimal neuromuscular benefit and tolerability in the opinion of the investigator. In order to continue in the study, treatment-naïve patients were required to have an improvement of at least three points in the quantitative myasthenia gravis score from the initial evaluation. For its pediatric indication, use is supported by evidence from studies of Firdapse in adults with LEMS, pharmacokinetic data in adults, pharmacokinetic modeling and simulation to identify the dosing regimen in pediatric patients, and safety data from pediatric patients ≥ 6 years of age.

Safety

Firdapse and Ruzurgi are contraindicated in patients with a history of seizures.^{1,2} There is also a Warning/Precaution in the prescribing information for these medications because seizures have been observed in patients with and without a history of seizures taking amifampridine at the recommended doses.

07/31/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Many of these patients were taking medications or had comorbidities that may have lowered their seizure threshold. Seizures may be dose-dependent.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of amifampridine. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with amifampridine as well as the monitoring required for adverse events and long-term efficacy, initial approval requires amifampridine to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of amifampridine is recommended in those who meet the following criteria:

FDA-Approved Indications

5. **Lambert-Eaton Myasthenic Syndrome (LEMS).** Approve amifampridine for the duration noted if the patient meets ONE of the following (A or B):
 - A) **Initial therapy.** Approve amifampridine for 3 months if the patient meets ALL of the following (i, ii, iii, and iv):
 - i. Patient is ≥ 6 years of age; AND
 - ii. Patient has confirmed LEMS based on at least ONE of the following, according to the prescriber:
 - 1) Electrodiagnostic study (e.g., repetitive nerve stimulation); OR
 - 2) Anti-P/Q-type voltage-gated calcium channels antibody testing; AND
 - iii. Patient does not have a of seizures; AND
 - iv. Amifampridine is being prescribed by or in consultation with a neurologist or a neuromuscular specialist; OR
 - B) **Patient is Currently Receiving amifampridine.** Approve amifampridine for 1 year if the patient is continuing to derive benefit from amifampridine, according to the prescriber.
Note: Examples of continued benefit include improved muscle strength and improvements in mobility.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of amifampridine is not recommended in the following situations:

2. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Amyloidosis – Amvuttra Prior Authorization Policy

- Amvuttra™ (vutrisiran subcutaneous injection – Alnyam)

REVIEW DATE: 12/04/2024

OVERVIEW

Amvuttra, a transthyretin (TTR)-directed small interfering RNA, is indicated for the treatment of **polyneuropathy of hereditary transthyretin-mediated amyloidosis (hATTR)** in adults.¹ Amvuttra has not been studied in patients with prior liver transplantation.⁴

Disease Overview

hATTR is a progressive disease caused by variants in the TTR gene leading to multisystem organ dysfunction.² Common neurologic manifestations include sensorimotor polyneuropathy, autonomic neuropathy, small-fiber polyneuropathy, and carpal tunnel syndrome.

Guidelines

There are no guidelines that include recommendations for Amvuttra. A scientific statement from the American Heart Association (AHA) on the treatment of the cardiomyopathy of hATTR amyloidosis (July 2020) includes recommendations related to polyneuropathy.³ Canadian guidelines for the treatment of patients with polyneuropathy (February 2021) include treatment recommendations for hATTR polyneuropathy as well.² In general, Onpattro® (patisiran intravenous infusion) and Tegsedi® (inotersen subcutaneous injection) are recommended for patients with hATTR polyneuropathy.

For patients with hATTR amyloidosis with polyneuropathy, the AHA recommends treatment with Onpattro or Tegsedi.³ For patients with hATTR with polyneuropathy and cardiomyopathy, Onpattro, Tegsedi, or Vyndamax® (tafamidis meglumine capsules)/Vyndaqel™ (tafamidis capsules) are recommended. Use of combination therapy is discussed; however, it is noted that there is little data to support combination therapy.

The Canadian guidelines recommend Onpattro and Tegsedi as first-line treatment to stop the progression of neuropathy and improve polyneuropathy in early and late stage hATTR amyloidosis with polyneuropathy.²

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Amvuttra. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Amvuttra as well as the monitoring required for adverse events and long-term efficacy, approval requires Amvuttra to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Amvuttra is recommended in those who meet the following criteria:

FDA-Approved Indication

1. **Polyneuropathy of Hereditary Transthyretin-Mediated Amyloidosis (hATTR).** Approve for 1 year if the patient meets ALL of the following (A, B, C, D, and E):
 - A) Patient is ≥ 18 years of age; AND
 - B) Patient has a transthyretin pathogenic variant as confirmed by genetic testing; AND
 - C) Patient has symptomatic polyneuropathy; AND
Note: Examples of symptomatic polyneuropathy include reduced motor strength/coordination, and impaired sensation (e.g., pain, temperature, vibration, touch). Examples of assessments for symptomatic disease include history and clinical exam, electromyography, or nerve conduction velocity testing.
 - D) Patient does not have a of liver transplantation; AND
 - E) The medication is prescribed by or in consultation with a neurologist, geneticist, or a physician who specializes in the treatment of amyloidosis.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Amvuttra is not recommended in the following situations:

3. **Concurrent use with other medications indicated for the treatment of polyneuropathy of hereditary transthyretin-mediated amyloidosis or transthyretin-mediated amyloidosis-cardiomyopathy (e.g., Attruby [acoramidis tablets], Onpattro [patisiran intravenous infusion], Tegsedi [inotersen subcutaneous injection], Wainua [eplontersen subcutaneous injection], or a tafamidis product).**
The requested medication should not be administered in combination with other medications indicated for polyneuropathy of hereditary transthyretin-mediated amyloidosis or transthyretin-mediated amyloidosis-cardiomyopathy. Combination therapy is generally not recommended due to a lack of controlled clinical trial data supporting additive efficacy.
4. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Amyloidosis – Acoramidis Prior Authorization Policy

- Attruby (acoramidis tablets – Bridgebio)

REVIEW DATE: 12/04/2024

OVERVIEW

Attruby, a transthyretin (TTR) stabilizer, is indicated for the treatment of the **cardiomyopathy of wild-type or variant TTR-mediated amyloidosis (ATTR-CM)** to reduce cardiovascular death and cardiovascular-related hospitalization in adults.¹ Studies excluded patients with New York Heart Association class IV disease.²

Disease Overview

ATTR-CM is a progressive, debilitating, and life-threatening disease that may go unrecognized and result in late-stage diagnosis.^{3,4} ATTR can be caused by an acquired wild-type variant or be an inherited variant that alters the structure and function of TTR. Genetic testing of the TTR gene is done to differentiate patients with the wild-type vs. a genetic variant. Although patients with ATTR may present with a variety of symptoms, neuropathy or cardiomyopathy are often the most prominent symptoms. Patients may also present with a mixed phenotype and exhibit signs of both neuropathy and cardiomyopathy. In ATTR-CM, the stability of the TTR tetramer is altered, resulting in misfolding of the TTR protein. This leads to accumulation of amyloid in the body, most commonly the myocardium and peripheral nerves. As a result of amyloid deposits in cardiac tissue and causes the heart muscle becomes stiff and rigid. Although the clinical course varies, patients typically exhibit heart failure with preserved ejection fraction. However, some patients may present with right-sided heart failure, atrial fibrillation, aortic stenosis and complete heart block, angina, or cardiogenic shock.

Guidelines

Attruby is currently not addressed in guidelines. The American Heart Association (AHA) scientific statement for the evolving diagnosis and management of cardiac amyloidosis (2020) recognizes tafamidis as a treatment for ATTR-CM.⁵ They note that the benefit of tafamidis has not been observed in patients with NYHA class IV symptoms. Additionally, although combination use of tafamidis with Onpattro® (patisiran lipid complex intravenous infusion) or Tegsedi® (inotersen subcutaneous injection) is appealing to target both TTR silencing and stabilization for the remaining synthesized protein, this approach lacks data and may be cost-prohibitive. Tafamidis should generally be considered the agent of choice in ATTR-CM in patients with reasonable expected survival according to a position statement of the European Society of Cardiology (ESC) working group on myocardial and pericardial disease (2021).⁶ The working group notes that tafamidis is the only drug that has shown efficacy in a randomized trial in patients with ATTR-CM and should be considered in patients with reasonable expected survival. The American College of Cardiology (ACC) expert consensus decision pathway on comprehensive multidisciplinary care for patients with cardiac amyloidosis (2023) make similar comments and recommendations to the AHA and ESC regarding tafamidis.⁷

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Attruby. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Attruby as well as the monitoring required for adverse events and long-

12/04/2024

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

term efficacy, initial approval requires the agent to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Attruby is recommended in those who meet the following criteria:

FDA-Approved Indication

- 1. Cardiomyopathy of Wild-Type or Hereditary Transthyretin-Mediated Amyloidosis (ATTR-CM).** Approve for 1 year if the patient meets ALL of the following (A, B, C, D, and E):

Note: Variant Transthyretin Amyloidosis is also known as Hereditary Transthyretin Amyloidosis.

A) Patient is ≥ 18 years of age; AND

B) The diagnosis was confirmed by ONE of the following (i, ii, or iii):

i. A technetium pyrophosphate scan (i.e., nuclear scintigraphy); OR

ii. A tissue biopsy with confirmatory transthyretin (TTR) amyloid typing by mass spectrometry, immunoelectron microscopy or immunohistochemistry; OR

iii. Patient had genetic testing which, according to the prescriber, identified a transthyretin (TTR) pathogenic variant; AND

Note: Examples of TTR variants include Val122Ile variant and Thr60Ala variant. If the patient has wild-type amyloidosis, this is **not** a TTR pathogenic variant.

C) Diagnostic cardiac imaging has demonstrated cardiac involvement; AND

Note: Examples of cardiac imaging include echocardiogram and cardiac magnetic imaging. Examples of cardiac involvement on imaging include increased thickness of the ventricular wall or interventricular septum.

D) Patient has heart failure, but does **not** have New York Heart Association class IV disease; AND

E) The medication is prescribed by or in consultation with a cardiologist or a physician who specializes in the treatment of amyloidosis.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Attruby is not recommended in the following situations:

- 5. Concurrent use with other medications indicated for the treatment of polyneuropathy of hereditary transthyretin-mediated amyloidosis or transthyretin-mediated amyloidosis-cardiomyopathy (e.g., Amvuttra [vutrisiran subcutaneous injection], Onpattro [patisiran intravenous infusion], Tegsedi [inotersen subcutaneous injection], Wainua [eplontersen subcutaneous injection], or a tafamidis product).**

The requested medication should not be administered in combination with other medications indicated for polyneuropathy of hereditary transthyretin-mediated amyloidosis or transthyretin-mediated amyloidosis-cardiomyopathy. Combination therapy is generally not recommended due to a lack of controlled clinical trial data supporting additive efficacy.

- 2. Polyneuropathy of Hereditary Transthyretin-Mediated Amyloidosis (hATTR).** Attruby is not indicated for treatment of symptoms of polyneuropathy associated with hATTR.¹

Note: For patients with hATTR and cardiomyopathy or mixed phenotype (concurrent cardiomyopathy and polyneuropathy), refer to FDA-Approved Indication, above.

3. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Amyloidosis – Onpattro Prior Authorization Policy

- Onpattro® (patisiran intravenous infusion – Alnylam)

REVIEW DATE: 12/04/2024

OVERVIEW

Onpattro, a lipid nanoparticle formulated RNA interference therapeutic, is indicated for treatment of adults with **polyneuropathy of hereditary amyloid transthyretin amyloidosis (hATTR)**.¹ hATTR is a progressive disease caused by mutations in the transthyretin (TTR) gene leading to multisystem organ dysfunction.² Common neurologic manifestations include sensorimotor polyneuropathy, autonomic neuropathy, small-fiber polyneuropathy, and carpal tunnel syndrome.

Clinical Efficacy

The pivotal trial for Onpattro did not include patients with liver transplantation, which has historically been a treatment modality for hATTR.^{1,6} A Phase IIIb, open-label trial evaluated the efficacy of Onpattro in adults with hATTR polyneuropathy progression post liver transplant (n = 23).⁶ Patients received Onpattro at the FDA-approved dose for 12 months. The average of Month 6 and Month 12 serum TTR reduction was 91%. In addition, improvements in neuropathy, quality of life, autonomic symptoms from baseline to Month 12, and stabilized disability and nutritional status was noted. The prescribing information for Onpattro notes that age, race (non-Caucasian vs. Caucasian), sex, and prior liver transplantation had no impact on the steady state pharmacokinetics of Onpattro or TTR reduction.¹

APOLLO-B was a Phase III, double-blind, trial that randomized patients with hATTR cardiac amyloidosis to receive Onpattro or placebo for 12 months (n = 360).⁷ The primary endpoint was a change from baseline in the distance walked on 6-minute walk test. The first secondary endpoint was the change from baseline to Month 12 in the Kansas City Cardiomyopathy Questionnaire-Overall Summary (KCCQ-OS) score. A composite of death from any cause, cardiovascular events, and change from baseline in the 6-minute walk test distance over 12 months, was a secondary endpoint. A third secondary endpoint assessed the composite of death from any cause, hospitalization for any cause, and urgent heart failure visits. At Month 12, the magnitude of decline in 6-minute walk distance was significantly lower in the Onpattro group (-8.15 meters) vs. placebo (-21.35 meters) [median difference 14.69 meters; 95% confidence interval [CI]: 0.69, 28.69; P = 0.02]. The KCCQ-OS score was slightly improved with Onpattro (+0.3 points), but reduced with placebo (-3.4 points), leading to a statistically significant between group difference (3.7 points; 95% CI: 0.2, 7.2; P = 0.04). The secondary composite endpoints were not significant between groups. Based on these findings, the FDA cited insufficient evidence of clinical meaningfulness for the treatment of cardiomyopathy of hATTR and issued a complete response letter to the manufacturer of Onpattro for the treatment of cardiomyopathy of hATTR.⁸

Guidelines

A scientific statement from the American Heart Association (AHA) on the treatment of cardiomyopathy of hATTR amyloidosis (July 2020) includes recommendations related to polyneuropathy.³ Canadian guidelines for the treatment of patients with polyneuropathy (February 2021) and recommendations from the European Society of Cardiology (ESC) [2021] include treatment recommendations for hATTR polyneuropathy as well.^{2,4} The American College of Cardiology (ACC) expert consensus decision pathway on comprehensive multidisciplinary care for patients with cardiac amyloidosis (2023) mention Onpattro for polyneuropathy of hATTR; but, it is noted that the product is not indicated for cardiomyopathy of hATTR

12/04/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

amyloidosis (APOLLO-B trial results are acknowledged).⁹ In general, Onpattro and Tegsedi® (inotersen subcutaneous injection) are recommended for patients with hATTR polyneuropathy.

For patients with hATTR amyloidosis with polyneuropathy, the AHA recommends treatment with Onpattro or Tegsedi.³ For patients with hATTR with polyneuropathy and cardiomyopathy, Onpattro, Tegsedi, or Vyndamax™ (tafamidis capsules)/Vyndaqel® (tafamidis meglumine capsules) are recommended. Use of combination therapy is discussed; however, it is noted that there is little data to support combination therapy.

The Canadian guidelines recommend Onpattro and Tegsedi as first-line treatment to stop the progression of neuropathy and improve polyneuropathy in early and late stage hATTR amyloidosis with polyneuropathy.²

The ESC Guidelines for the diagnosis and treatment of acute and chronic heart failure note that TTR stabilization and reduction are the recommended basis of treatment for cardiomyopathy of ATTR.⁴ Onpattro and Tegsedi may be considered for patients with hATTR polyneuropathy and cardiomyopathy.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Onpattro. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Onpattro as well as the monitoring required for adverse events and long-term efficacy, approval requires Onpattro to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Onpattro is recommended in those who meet the following criteria:

FDA-Approved Indication

1. Polyneuropathy of Hereditary Transthyretin-Mediated Amyloidosis (hATTR). Approve for 1 year if the patient meets ALL of the following (A, B, C, and D):

F) Patient is ≥18 years of age; AND

G) Patient has a transthyretin pathogenic variant as confirmed by genetic testing; AND

H) Patient has symptomatic polyneuropathy; AND

Note: Examples of symptomatic polyneuropathy include reduced motor strength/coordination, and impaired sensation (e.g., pain, temperature, vibration, touch). Examples of assessments for symptomatic disease include and clinical exam, electromyography, or nerve conduction velocity testing.

I) The medication is prescribed by or in consultation with a neurologist, geneticist, or a physician who specializes in the treatment of amyloidosis.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Onpattro is not recommended in the following situations:

4. **Concurrent use with other medications indicated for the treatment of polyneuropathy of hereditary transthyretin-mediated amyloidosis or transthyretin-mediated amyloidosis-cardiomyopathy (e.g., Amvuttra [vutrisiran subcutaneous injection], Attriby [acoramidis tablets], Tegsedi [inotersen subcutaneous injection], Wainua [eplontersen subcutaneous injection], or a tafamidis product.)**

The requested medication should not be administered in combination with other medications indicated for polyneuropathy of hereditary transthyretin-mediated amyloidosis or transthyretin-mediated amyloidosis-cardiomyopathy. Combination therapy is generally not recommended due to a lack of controlled clinical trial data supporting additive efficacy.

5. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Amyloidosis – Tafamidis Products Prior Authorization Policy

- Vyndaqel (tafamidis meglumine capsules – Pfizer)
- Vyndamax (tafamidis capsules – Pfizer)

REVIEW DATE: 12/04/2024

OVERVIEW

Vyndaqel and Vyndamax are selective stabilizers of transthyretin (TTR) indicated for the treatment of the **cardiomyopathy of wild-type or hereditary TTR-mediated amyloidosis (ATTR-CM)** to reduce cardiovascular mortality and cardiovascular-related hospitalization in adults.¹ Studies excluded patients with New York Heart Association class IV disease.²

Disease Overview

In ATTR-CM, there is misfolding of the TTR protein resulting in accumulation of amyloid in the heart causing thickening of both ventricles.²⁻⁸ ATTR-CM may be suspected following cardiac imaging (e.g., echocardiogram, cardiac magnetic imaging). Subsequent testing (e.g., scintigraphy or biopsy) confirms the diagnosis of ATTR-CM. Endomyocardial biopsy confirms the diagnosis of ATTR-CM.⁸ Biopsy can confirm if ATTR-CM is due to a hereditary mutant variant of TTR vs. an acquired wild-type variant. In patients with confirmed cardiac amyloidosis, TTR gene sequencing aids in treatment decisions and is necessary for genetic counseling in relatives of patients with a TTR variant.⁷ Although many mutations have been identified, mutation of V122I is the most common in the US.²⁻⁶ This mutation is present in 3% to 4% of African Americans and is associated with amyloid cardiomyopathy. Vyndaqel and Vyndamax bind to TTR at the thyroxine binding sites and stabilize the tetramer. This slows dissociation into monomers, which is the rate-limiting step in the amyloidogenic process.¹

Guidelines

The American Heart Association (AHA) scientific statement for the evolving diagnosis and management of cardiac amyloidosis (2020) recognizes tafamidis as a treatment for ATTR-CM.⁷ They note that the benefit of tafamidis has not been observed in patients with NYHA class IV symptoms. Additionally, although combination use of tafamidis with Onpattro® (patisiran lipid complex intravenous infusion) or Tegsedi® (inotersen subcutaneous injection) is appealing to target both TTR silencing and stabilization for the remaining synthesized protein, this approach lacks data and may be cost-prohibitive. Tafamidis should generally be considered the agent of choice in ATTR-CM in patients with reasonable expected survival according to a position statement of the European Society of Cardiology (ESC) working group on myocardial and pericardial disease (2021).⁸ The working group notes that tafamidis is the only drug that has shown efficacy in a randomized trial in patients with ATTR-CM and should be considered in patients with reasonable expected survival. The American College of Cardiology (ACC) expert consensus decision pathway on comprehensive multidisciplinary care for patients with cardiac amyloidosis (2023) make similar comments and recommendations to the AHA and ESC regarding tafamidis.¹⁰

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of tafamidis products (Vyndaqel and Vyndamax). All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with tafamidis products (Vyndaqel and Vyndamax)

12/04/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

as well as the monitoring required for adverse events and long-term efficacy, initial approval requires the agent to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of tafamidis products (Vyndaqel and Vyndamax) is recommended in those who meet the following criteria:

FDA-Approved Indication

2. Cardiomyopathy of Wild-Type or Hereditary Transthyretin-Mediated Amyloidosis (ATTR-CM). Approve for 1 year if the patient meets ALL of the following (A, B, C, D, and E):

Note: Variant Transthyretin Amyloidosis is also known as Hereditary Transthyretin Amyloidosis.

F) Patient is ≥ 18 years of age; AND

G) The diagnosis was confirmed by ONE of the following (i, ii, or iii):

i. A technetium pyrophosphate scan (i.e., nuclear scintigraphy); OR

ii. A tissue biopsy with confirmatory transthyretin (TTR) amyloid typing by mass spectrometry, immunoelectron microscopy or immunohistochemistry; OR

iii. Patient had genetic testing which, according to the prescriber, identified a transthyretin (TTR) pathogenic variant; AND

Note: Examples of TTR variants include Val122Ile variant and Thr60Ala variant. If the patient has wild-type amyloidosis, this is **not** a TTR pathogenic variant.

H) Diagnostic cardiac imaging has demonstrated cardiac involvement; AND

Note: Examples of cardiac imaging include echocardiogram and cardiac magnetic imaging. Examples of cardiac involvement on imaging include increased thickness of the ventricular wall or interventricular septum.

I) Patient has heart failure, but does **not** have New York Heart Association class IV disease; AND

J) The medication is prescribed by or in consultation with a cardiologist or a physician who specializes in the treatment of amyloidosis.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of tafamidis products (Vyndaqel and Vyndamax) is not recommended in the following situations:

6. Concurrent use with other medications indicated for the treatment of polyneuropathy of hereditary transthyretin-mediated amyloidosis or transthyretin-mediated amyloidosis-cardiomyopathy (e.g., Amvuttra [vutrisiran subcutaneous injection], Attriby [acoramidis tablets], Onpattro [patisiran lipid complex intravenous infusion], Tegsedi [inotersen subcutaneous injection], or Wainua [eplontersen subcutaneous injection]).

The requested medication should not be administered in combination with other medications indicated for polyneuropathy of hereditary transthyretin-mediated amyloidosis or transthyretin-mediated amyloidosis-cardiomyopathy. Combination therapy is generally not recommended due to a lack of controlled clinical trial data supporting additive efficacy.

7. Concurrent Use of Vyndaqel and Vyndamax. There are no data available to support concomitant use.¹

8. **Polyneuropathy of Hereditary Transthyretin–Mediated Amyloidosis (hATTR).** Neither Vyndaqel nor Vyndamax are indicated for treatment of symptoms of polyneuropathy associated with hATTR.¹

Note: For patients with hATTR and cardiomyopathy or mixed phenotype (concurrent cardiomyopathy and polyneuropathy), refer to FDA-Approved Indication, above.

9. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Amyloidosis – Tegsedi Prior Authorization Policy

- Tegsedi® (inotersen subcutaneous injection – Ionis/Akcea Therapeutics)

REVIEW DATE: 12/04/2024

OVERVIEW

Tegsedi, an antisense oligonucleotide, is indicated for treatment of adults with **polyneuropathy of hereditary transthyretin-mediated amyloidosis (hATTR)**.¹ Tegsedi has not been studied in patients with a history of liver transplantation. hATTR is a progressive disease caused by mutations in the transthyretin (TTR) gene leading to multisystem organ dysfunction.² Common neurologic manifestations include sensorimotor polyneuropathy, autonomic neuropathy, small-fiber polyneuropathy, and carpal tunnel syndrome.

Guidelines

A scientific statement from the American Heart Association (AHA) on the treatment of cardiomyopathy of hATTR (July 2020) includes recommendations related to polyneuropathy.³ Canadian guidelines for the treatment of patients with polyneuropathy (February 2021) and recommendations from the European Society of Cardiology (ESC) [2021] include treatment recommendations for hATTR polyneuropathy as well.^{2,4} The American College of Cardiology (ACC) expert consensus decision pathway on comprehensive multidisciplinary care for patients with cardiac amyloidosis (2023) mention Tegsedi for polyneuropathy of hATTR.⁵ In general, Onpattro and Tegsedi are recommended for patients with hATTR polyneuropathy.

For patients with hATTR with polyneuropathy, the AHA recommends treatment with Onpattro or Tegsedi.³ For patients with hATTR with polyneuropathy and cardiomyopathy, Onpattro, Tegsedi, or Vyndamax/Vyndaqel are recommended. Use of combination therapy is discussed; however, it is noted that there is little data to support combination therapy.

The Canadian guidelines recommend Onpattro and Tegsedi as first-line treatment to stop the progression of neuropathy and improve polyneuropathy in early and late stage hATTR with polyneuropathy.²

The ESC Guidelines for the diagnosis and treatment of acute and chronic heart failure note that TTR stabilization and reduction are the recommended basis of treatment for cardiomyopathy of hATTR.⁴ Onpattro and Tegsedi may be considered for patients with hATTR polyneuropathy and cardiomyopathy.

Safety

Tegsedi has a Boxed Warning regarding sudden and unpredictable thrombocytopenia which may be life-threatening.¹ It is contraindicated in patients with a platelet count less than $100 \times 10^9/L$. Based on monitoring, Tegsedi may need to be interrupted or discontinued. Following discontinuation, continue to monitor platelet counts for 8 weeks (or longer if platelet count is less than $100 \times 10^9/L$). Tegsedi also has a Boxed Warning regarding glomerulonephritis, which may require immunosuppressive treatment and may lead to dialysis-dependent renal failure. Due to the risks and frequent monitoring for both serious bleeding caused by severe thrombocytopenia and because of glomerulonephritis, Tegsedi is only available through a restricted distribution program under the Tegsedi REMS (Risk Evaluation and Mitigation Strategy).

12/04/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Tegsedi. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Tegsedi as well as the monitoring required for adverse events and long-term efficacy, approval requires Tegsedi to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Tegsedi is recommended in those who meet the following criteria:

FDA-Approved Indication

- 1. Polyneuropathy of Hereditary Transthyretin-Mediated Amyloidosis (hATTR).** Approve for 1 year if the patient meets ALL of the following (A, B, C, D, and E):
 - A)** Patient is ≥ 18 years of age; AND
 - B)** Patient has a transthyretin pathogenic variant as confirmed by genetic testing; AND
 - C)** Patient has symptomatic polyneuropathy; AND
Note: Examples of polyneuropathy include reduced motor strength/coordination, and impaired sensation (e.g., pain, temperature, vibration, touch). Examples of assessments for symptomatic disease include history and clinical exam, electromyography, or nerve conduction velocity testing.
 - D)** Patient does not have a of liver transplantation; AND
 - E)** The medication is prescribed by or in consultation with a neurologist, geneticist, or a physician who specializes in the treatment of amyloidosis.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Tegsedi is not recommended in the following situations:

- 10. Concurrent use with other medications indicated for the treatment of polyneuropathy of hereditary transthyretin-mediated amyloidosis or transthyretin-mediated amyloidosis-cardiomyopathy (e.g., Amvuttra [vutrisiran subcutaneous injection], Attruby [acoramidis tablets], Onpattro [patisiran lipid complex intravenous infusion], Wainua [eplontersen subcutaneous injection], or a tafamidis product).**
The requested medication should not be administered in combination with other medications indicated for polyneuropathy of hereditary transthyretin-mediated amyloidosis or transthyretin-mediated amyloidosis-cardiomyopathy. Combination therapy is generally not recommended due to a lack of controlled clinical trial data supporting additive efficacy.
- 11. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.**

PRIOR AUTHORIZATION POLICY

POLICY: Amyloidosis – Wainua Prior Authorization Policy

- Wainua™ (eplontersen subcutaneous injection – AstraZeneca)

REVIEW DATE: 12/04/2024

OVERVIEW

Wainua, a transthyretin (TTR)-directed antisense oligonucleotide, is indicated for the treatment of the **polyneuropathy of hereditary TTR-mediated amyloidosis (hATTR)** in adults.¹ Wainua has not been studied in patients with prior liver transplantation. hATTR is a progressive disease caused by mutations in the TTR gene leading to multisystem organ dysfunction.² Common neurologic manifestations include sensorimotor polyneuropathy, autonomic neuropathy, small-fiber polyneuropathy, and carpal tunnel syndrome.

Guidelines

There are no guidelines that include recommendations for Wainua. A scientific statement from the American Heart Association (AHA) on the treatment of the cardiomyopathy of hATTR amyloidosis (July 2020) includes recommendations related to polyneuropathy.³ Canadian guidelines for the treatment of patients with polyneuropathy (February 2021) and recommendations from the European Society of Cardiology (ESC) [2021] include treatment recommendations for hATTR polyneuropathy as well.^{2,4} In general, Onpattro® (patisiran intravenous infusion) and Tegsedi® (inotersen subcutaneous injection) are recommended for patients with hATTR polyneuropathy.

For patients with hATTR amyloidosis with polyneuropathy, the AHA recommends treatment with Onpattro or Tegsedi.³ For patients with hATTR with polyneuropathy and cardiomyopathy, Onpattro, Tegsedi, or Vyndamax® (tafamidis meglumine capsules)/Vyndaqel™ (tafamidis capsules) are recommended. Use of combination therapy is discussed; however, it is noted that there is little data to support combination therapy.

The Canadian guidelines recommend Onpattro and Tegsedi as first-line treatment to stop the progression of neuropathy and improve polyneuropathy in early and late stage hATTR amyloidosis with polyneuropathy.²

The ESC Guidelines for the diagnosis and treatment of acute and chronic heart failure note that TTR stabilization and reduction are the recommended basis of treatment for cardiomyopathy of hATTR.⁴ Onpattro and Tegsedi may be considered for patients with hATTR polyneuropathy and cardiomyopathy.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Wainua. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Wainua as well as the monitoring required for adverse events and long-term efficacy, approval requires Wainua to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

PRIOR AUTHORIZATION POLICY

POLICY: Antibiotics (Inhaled) – Arikayce Prior Authorization Policy

- Arikayce® (amikacin liposome suspension for oral inhalation – Insmed)

REVIEW DATE: 10/23/2024

OVERVIEW

Arikayce is indicated for the treatment of ***Mycobacterium avium complex (MAC) lung disease***, in adults who have limited or no alternative treatment options, as part of a combination antibacterial regimen in patients who do not achieve negative sputum cultures after at least 6 consecutive months of a background multidrug regimen (MDR) therapy.¹ As only limited clinical safety and efficacy data are available, reserve Arikayce for adults with limited or no other treatment options.

This indication was approved under accelerated approval based on achieving sputum culture conversion (defined as three consecutive negative monthly sputum cultures) by Month 6.¹

Limitation of Use: Arikayce has only been studied in patients with refractory MAC lung disease defined as not achieving culture negativity after at least 6 months of background MDR treatment.¹ Arikayce is not recommended in patients with non-refractory MAC lung disease.

Efficacy

The efficacy of Arikayce was established in one open-label, randomized (2:1), multi-center trial in patients with refractory MAC lung disease as confirmed by at least 2 sputum culture results (n = 336).⁷ Patients were considered to have refractory MAC lung disease if they did not achieve negative sputum cultures after a minimum duration of 6 consecutive months of background regimen therapy that was either ongoing or stopped ≤ 12 months before the screening visit. The surrogate efficacy endpoint was based on achieving culture conversion (3 consecutive monthly negative sputum cultures) by Month 6. Patients who achieved culture conversion by Month 6 were continued on Arikayce plus background multidrug regimen or background multidrug regimen alone based on their randomization for a total of 12 months after the first negative sputum culture. At baseline, 329 patients were on a multidrug background regimen that included a macrolide (93.3%), a rifamycin (86.3%), or ethambutol (81.4%). The proportion of patients achieving culture conversion by Month 6 was significantly greater with Arikayce plus background multidrug regimen vs. background multidrug regimen alone (29% vs. 8.9%, respectively; $P < 0.0001$). Among patients who achieved culture conversion by Month 6, 55.4% of patients in the Arikayce group vs. no patients in the background multidrug regimen only group had sustained and durable conversion ($P = 0.0017$).⁸ Relapse rates through 3 months after treatment were 9.2% in the Arikayce group vs. 30.0% in the background therapy only group.

Guidelines

The American Thoracic Society, the European Respiratory Society, the European Society of Clinical Microbiology and Infectious Disease, and the Infectious Disease Society of America developed clinical practice guidelines for the treatment of nontuberculous mycobacterial (NTM) pulmonary disease (2020).² Treatment recommendations for MAC lung disease are based on disease severity and previous therapies received and almost all are three drug regimens. Typical regimens involve azithromycin or clarithromycin; ethambutol; and rifampin. For select patients, a two-drug regimen consisting of azithromycin or clarithromycin plus ethambutol daily is acceptable. Liposomal amikacin is not recommended for the initial treatment of MAC pulmonary disease. The guidelines recommend the addition of liposomal amikacin to

10/23/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

guideline-based therapy in patients with MAC pulmonary disease who have failed treatment (failure to convert sputum culture) after ≥ 6 months of treatment with guideline-based therapy. Patients should be treated for ≥ 12 months after culture conversion. The breakpoint for resistance to amikacin is ≥ 64 mcg/mL for parenteral amikacin and ≥ 128 mcg/mL for amikacin liposome inhalation suspension, and finding these MICs would lead to cessation of therapy. In patients with MAC pulmonary disease, guidelines suggest susceptibility-based treatment for macrolides and amikacin over empiric therapy (conditional recommendation, very low certainty in estimates of effect).

The US Cystic Fibrosis Foundation and the European Cystic Fibrosis Society (2016 version) developed consensus recommendations on the treatment of NTM lung disease in which nebulized amikacin is listed as a treatment option for MAC and *M. abscessus* lung disease in cystic fibrosis (CF) patients.³ The guidelines recommend that inhaled amikacin be used in conjunction with other NTM antibiotics.

Other Uses with Supportive Evidence

The efficacy of Arikayce in the treatment of *Pseudomonas aeruginosa* infection in patients with CF has been assessed in three studies.⁴ In a Phase III, randomized, open-label, non-inferiority study, patients with CF were randomized to Arikayce 590 mg once daily (QD) or tobramycin inhalation solution (TIS) 300 mg twice daily (n = 302). Patients received three cycles of treatment which consisted of 28 days on treatment followed by 28 days off treatment. The primary endpoint of the study was the relative change from baseline to the end of the 24-week study in forced expiratory volume in 1 second (FEV₁). FEV₁ improvement at Day 168 with Arikayce was non-inferior to TIS (mean difference -1.31%). More patients receiving Arikayce experienced pulmonary exacerbations compared with TIS; however, fewer patients required all-cause hospitalization. Change in CF Questionnaire Revised was similar between groups at the end of each treatment course. Mean reductions in *P. aeruginosa* log₁₀ CFU was similar for Arikayce and TIS at Day 28 and at Day 140.

A pooled report included 24 patients with CF and chronic *P. aeruginosa* infection from two Phase Ib/IIa pharmacokinetic/pharmacodynamic studies.⁵ Patients received liposomal amikacin 500 mg QD by inhalation for 14 days. Statistically significant changes from baseline to Days 7 and 14 were seen in FEV₁, FEV₁ % predicted, and forced expiratory flow between 25% and 75% of forced vital capacity. Another report included pooled data from two dose-ranging studies (one Phase Ib/IIa and one Phase IIa) in patients with CF (n = 105) chronically infected with *P. aeruginosa*.⁶ Patients received 70-, 140-, 280- or 560-mg of liposomal amikacin or placebo QD for 28 days and were followed for an additional 28 days. In repeated-measures mixed-effect models, the 560 mg dose was associated with statistically significant improvements in FEV₁, and FEV₁ % predicted and a reduction in log₁₀ CFUs.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Arikayce. All approvals are provided for the duration noted below. In cases where the approval duration is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Arikayce as well as the monitoring required for adverse events and long-term efficacy, initial approval requires Arikayce to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Arikayce is recommended in those who meet one of the following criteria:

10/23/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

FDA-Approved Indication

2. ***Mycobacterium avium* Complex Lung Disease.** Approve for the duration noted if the patient meets ONE of the following (A or B):

A) Initial Therapy. Approve for 1 year if the patient meets ALL of the following (i, ii, iii, iv, v, and vi):

- i. Patient is ≥ 18 years of age; AND
- ii. Patient has completed ≥ 6 consecutive months of a background multidrug regimen; AND
Note: A multidrug regimen typically includes a macrolide (azithromycin or clarithromycin), ethambutol, and a rifamycin (rifampin or rifabutin).
- iii. Patient has a positive sputum culture for *Mycobacterium avium* complex; AND
Note: Any positive sputum culture taken after the patient has completed ≥ 6 consecutive months of a background multidrug regimen fulfills this criterion.
- iv. The *Mycobacterium avium* complex isolate is susceptible to amikacin, according to the laboratory report; AND
- v. The medication will be used in conjunction with a background multidrug regimen; AND
Note: A multidrug regimen typically includes a macrolide (azithromycin or clarithromycin), ethambutol, and a rifamycin (rifampin or rifabutin).
- vi. The medication is prescribed by a pulmonologist, infectious diseases physician, or a physician who specializes in the treatment of *Mycobacterium avium* complex lung infections.

B) Patient is Currently Receiving Arikayce. Approve for the duration noted below if the patient meets BOTH of the following (i and ii):

- i. The medication will be used in conjunction with a background multidrug regimen; AND
Note: A multidrug regimen typically includes a macrolide (azithromycin or clarithromycin), ethambutol, and a rifamycin (rifampin or rifabutin).
- ii. Patient meets ONE of the following (a or b):
 - a) Approve for 1 year if patient has not achieved negative sputum cultures for *Mycobacterium avium* complex; OR
 - b) Approve for 1 year (total) if patient has achieved negative sputum cultures for *Mycobacterium avium* complex for less than 12 months.
Note: Approve enough Arikayce to complete 12 months of therapy following a negative sputum culture for *Mycobacterium avium* complex.

Other Uses with Supportive Evidence

2. **Cystic Fibrosis.** Approve for 1 year if the patient meets the following (A and B):

- A) Patient has *Pseudomonas aeruginosa* in culture of the airway (e.g., sputum culture, oropharyngeal culture, bronchoalveolar lavage culture); AND
- B) The medication is prescribed by or in consultation with a pulmonologist or a physician who specializes in the treatment of cystic fibrosis.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Arikayce is not recommended in the following situations:

8. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Antibiotics (Inhaled) – Cayston Prior Authorization Policy

- Cayston® (aztreonam inhalation solution – Gilead)

REVIEW DATE: 03/27/2024

OVERVIEW

Cayston, a monobactam antibiotic, is indicated to improve respiratory symptoms in **cystic fibrosis** (CF) patients with *Pseudomonas aeruginosa*.¹ Safety and efficacy have not been established in pediatric patients < 7 years of age, in patients with forced expiratory volume in 1 second (FEV₁) < 25% or > 75% predicted, or in patients colonized with *Burkholderia cepacia*.

To reduce the development of drug-resistant bacteria and maintain the effectiveness of Cayston and other antibiotics, Cayston should be used to treat patients with CF known to have *P. aeruginosa* in the lungs.¹

Clinical Efficacy

An open-label study assessed inhaled aztreonam for the eradication of newly acquired *P. aeruginosa* in children aged 3 months to < 18 years of age (n = 105).² In total, 49 patients < 6 years of age were included in the study. Patients received inhaled aztreonam 75 mg three times daily for 28 days. At the end of treatment with inhaled aztreonam, 91.5% of the patients (n = 43/47) < 6 years of age were culture-negative for *P. aeruginosa* and 76.6% of patients (n = 36/47) < 6 years of age remained culture-negative 4 weeks after completing the course of therapy.

Guidelines

The Cystic Fibrosis Foundation (CFF) Pulmonary Therapeutics Committee provides recommendations for the use of chronic medications in the management of CF lung disease (2013).³ In patients ≥ 6 years of age with CF and moderate-to-severe lung disease with *P. aeruginosa* persistently present in cultures of the airways, the chronic use of inhaled aztreonam is strongly recommended to improve lung function and quality of life (QoL). For mild disease, the Committee recommends chronic use of inhaled aztreonam for patients ≥ 6 years of age with CF and *P. aeruginosa* persistently present in cultures of the airways, to improve lung function and QoL.

The CFF published a systematic review of the literature regarding eradication of initial *P. aeruginosa* infections to develop guidelines for effective prevention (2014).⁴ The recommendations pertaining to inhaled antibiotics are as follows: 1) Inhaled antibiotic therapy is recommended for the treatment of initial or new growth of *P. aeruginosa* (the favored antibiotic regimen is tobramycin [300 mg twice daily] for 28 days); and 2) Prophylactic antipseudomonal antibiotics to prevent the acquisition of *P. aeruginosa* are not recommended.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Cayston. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Cayston as well as the monitoring required for adverse events and long-term efficacy, approval requires Cayston to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Cayston is recommended in those who meet one of the following:

FDA-Approved Indication

3. **Cystic Fibrosis.** Approve for 1 year if the patient meets BOTH of the following (A and B):
 - A) Patient has *Pseudomonas aeruginosa* in culture of the airway; AND
Note: Examples of culture of the airway include sputum culture, oropharyngeal culture, bronchoalveolar lavage culture.
 - B) The medication is prescribed by or in consultation with a pulmonologist or a physician who specializes in the treatment of cystic fibrosis.

Other Uses with Supportive Evidence

4. **Continuation of Cayston.** Approve for 1 month if the patient was started on Cayston and is continuing a course of therapy.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Cayston is not recommended in the following situations:

9. **Nasal Rinse.** Cayston is not approvable for compounding of aztreonam nasal rinse.
10. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Antibiotics (Inhaled) – TOBI Podhaler Prior Authorization Policy

- TOBI® Podhaler (tobramycin inhalation powder – Novartis)

REVIEW DATE: 03/27/2024

OVERVIEW

TOBI Podhaler, an aminoglycoside antibiotic, is indicated for the management of **cystic fibrosis** (CF) patients with *Pseudomonas aeruginosa*.¹ Safety and efficacy have not been demonstrated in patients < 6 years of age, patients with forced expiratory volume in 1 second (FEV₁) < 25% or > 80% predicted, or patients colonized with *Burkholderia cepacia*.

Guidelines

The Cystic Fibrosis Foundation (CFF) Pulmonary Therapeutics Committee (2013) provides recommendations for the use of chronic medications in the management of CF lung disease.² In patients ≥ 6 years of age with CF and moderate-to-severe lung disease with *P. aeruginosa* persistently present in cultures of the airways, the chronic use of inhaled tobramycin is strongly recommended to improve lung function, quality of life, and reduce exacerbations. For mild disease, the Committee recommends chronic use of inhaled tobramycin for patients ≥ 6 years of age with CF and *P. aeruginosa* persistently present in cultures of the airways, to reduce exacerbations.

The CFF published a systematic review of the literature regarding eradication of initial *P. aeruginosa* infections to develop guidelines for effective prevention (2014).³ The recommendations pertaining to inhaled antibiotics are as follows: 1) Inhaled antibiotic therapy is recommended for the treatment of initial or new growth of *P. aeruginosa* (the favored antibiotic regimen is tobramycin [300 mg twice daily] for 28 days); and 2) Prophylactic antipseudomonal antibiotics to prevent the acquisition of *P. aeruginosa* are not recommended.

The American Thoracic Society (ATS) published a clinical review (2013) of non-cystic fibrosis bronchiectasis on their webpage.⁴ The review lists nebulized antibiotics (e.g., colistin, gentamicin, tobramycin) as treatment options for the eradication or suppression of *P. aeruginosa*. The European Respiratory Society (ERS) have published guidelines (2017) for the management of adult bronchiectasis and recommends patients with a new isolate of *P. aeruginosa* be offered eradication antibiotic treatment which includes nebulized antibiotics (e.g., colistin, gentamicin, tobramycin).⁵ Neither the ATS nor the ERS guidelines include Tobi Podhaler® (tobramycin inhalation powder) as a treatment option for bronchiectasis and no clinical trials have been published with Tobi Podhaler for treatment of non-cystic fibrosis bronchiectasis.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of TOBI Podhaler. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with TOBI Podhaler as well as the monitoring required for adverse events and long-term efficacy, approval requires TOBI Podhaler to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

PRIOR AUTHORIZATION POLICY

- POLICY:** Antibiotics (Inhaled) – Tobramycin Inhalation Solution Prior Authorization Policy
- Bethkis® (tobramycin inhalation solution – Chiesi, generic)
 - Kitabis® (tobramycin inhalation solution – Pari, authorized generic)
 - TOBI® (tobramycin inhalation solution – Mylan, generic)

REVIEW DATE: 03/27/2024

OVERVIEW

The tobramycin inhalation solutions are aminoglycoside antibiotics indicated for the management of **cystic fibrosis (CF)** in patients with *Pseudomonas aeruginosa*.¹⁻³ TOBI (generic) and Kitabis (authorized generic) are indicated for the management of CF in patients ≥ 6 years of age.^{1,2} Safety and efficacy have not been demonstrated in patients < 6 years of age, patients with forced expiratory volume in 1 second (FEV₁) $< 25\%$ or $> 75\%$ predicted, or patients colonized with *Burkholderia cepacia*. Bethkis (generic) is indicated for the management of CF patients with *P. aeruginosa*.³ Safety and efficacy have not been demonstrated in patients < 6 years of age, patients with FEV₁ $< 40\%$ or $> 80\%$ predicted, or patients colonized with *B. cepacia*.

Guidelines

The Cystic Fibrosis Foundation (CFF) Pulmonary Therapeutics Committee published recommendations for the use of chronic medications in the management of CF lung disease (2013).⁴ In patients ≥ 6 years of age with CF and moderate-to-severe lung disease with *P. aeruginosa* persistently present in cultures of the airways, chronic use of inhaled tobramycin is strongly recommended to improve lung function, quality of life and reduce exacerbations. For mild disease, the Committee recommends chronic use of inhaled tobramycin for patients ≥ 6 years of age with CF and *P. aeruginosa* persistently present in cultures of the airways, to reduce exacerbations.

The CFF published a systematic review of the literature regarding eradication of initial *P. aeruginosa* infections to develop guidelines for effective prevention (2014).⁵ The recommendations pertaining to inhaled antibiotics are as follows: 1) Inhaled antibiotic therapy is recommended for the treatment of initial or new growth of *P. aeruginosa* (the favored antibiotic regimen is tobramycin [300 mg twice daily {BID}] for 28 days); and 2). Prophylactic antipseudomonal antibiotics to prevent the acquisition of *P. aeruginosa* are not recommended.

Other Uses with Supportive Evidence

A few trials support the efficacy of tobramycin inhalation solution (TIS) for the treatment of bronchiectasis with *P. aeruginosa* infection. A literature review concluded that in patients with non-CF bronchiectasis and chronic *P. aeruginosa* infection, TIS is effective in reducing the density of bacteria in sputum, which may be associated with additional clinical benefit.¹²

In a randomized, double-blind, placebo-controlled study, patients received either TIS 300 mg (n = 37) or placebo (n = 37) BID for 4 weeks and were followed for an additional 2 weeks off treatment.⁶ At Week 4, the TIS group had a mean 4.54 log₁₀ decrease in *P. aeruginosa* colony-forming units (CFU)/g of sputum compared with no change in the placebo group (P < 0.01). At Week 6, complete eradication of *P. aeruginosa* occurred in 35% of the patients in the TIS group compared with none in the placebo group, and 62% of patients in the TIS group vs. 38% of patients in the placebo group had improvements in their general health (odds ratio 2.7; 95% confidence interval: 1.1, 6.9).

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

In a randomized, single-blind study, patients received TIS 300 mg (n = 16) or placebo (n = 19) BID for 3 months following a 14-day course of intravenous ceftazidime and tobramycin and were followed for an additional 12 months.⁷ At the end of the study, 54.5% of patients in the TIS group (n = 6/11) and 29.4% of patients in the placebo group (n = 5/17) were free of *P. aeruginosa* (P = 0.048). In addition, patients in the TIS group had significantly fewer exacerbations (1.27 vs. 2.5; P = 0.044), hospital admissions (0.06 vs. 0.47; P = 0.037), and hospital days (0.9 vs. 13.56; P = 0.034) than patients in the placebo group, respectively. No significant differences were found in pulmonary function tests.

A double-blind, placebo-controlled, crossover study randomized 30 patients to initial TIS 300 mg or placebo BID for 6 months, followed by a 1 month washout period and 6 months of therapy with the other treatment.⁸ During the first treatment period, TIS treatment resulted in a significant reduction in *P. aeruginosa* density compared with placebo (P = 0.038). During both treatment periods, patients treated with TIS had fewer hospital admissions (0.15 vs. 0.75; P = 0.038) and hospital days (2.05 vs. 12.65; P = 0.047) than patients treated with placebo, respectively. No significant changes in the number of exacerbations and/or pulmonary function tests were observed.

In an open-label trial, 41 patients received three cycles of TIS 300 mg BID for 14 days followed by 14 days off therapy.⁹ Patients were followed for an additional 40 weeks after the three cycles of treatment with TIS. At Week 10, there was a significant improvement from baseline (mean change 1.5 points; P = 0.006) in the composite pulmonary symptom score which included cough, shortness of breath, sputum production, fatigue, and wheezing. Quality of life, assessed using the St. George's Respiratory Questionnaire, was significantly improved at Week 10 (mean change 9.8; P < 0.001) compared with baseline. At Week 12, 22.2% of patients (n = 6/27) were considered to have *P. aeruginosa* eradicated from sputum cultures.

A Phase III, multicenter, double-blind, placebo-controlled trial randomized adults with symptomatic bronchiectasis with positive *P. aeruginosa* sputum culture to TIS 300 mg (n = 167) or placebo (n = 172) in addition to standard of care.¹³ Treatment was provided for two cycles, each consisting of 28 days on therapy and 28 days off therapy. At Week 16, there was a significant reduction in *P. aeruginosa* density with TIS vs. placebo (adjusted difference 1.74 log₁₀ CFU/g; P < 0.001) and a greater improvement in the quality of life bronchiectasis respiratory symptom score on Day 29 (adjusted mean difference 7.91; P < 0.001). Significantly more patients were culture-negative for *P. aeruginosa* in the TIS group vs. placebo on Day 29 (29.3% vs. 10.6%, respectively).

The American Thoracic Society (ATS) published a clinical review (2013) of non-cystic fibrosis bronchiectasis.¹⁰ The review lists nebulized antibiotics (e.g., colistin, gentamicin, tobramycin) as treatment options for the eradication or suppression of *P. aeruginosa*. The European Respiratory Society (ERS) have published guidelines (2017) for the management of adult bronchiectasis and recommends patients with a new isolate of *P. aeruginosa* be offered eradication antibiotic treatment which includes nebulized antibiotics (e.g., colistin, gentamicin, tobramycin).¹¹ While both the ATS and ERS list nebulized colistin and gentamicin as treatment options for non-cystic fibrosis bronchiectasis, neither drug has a commercially available formulation for nebulization.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of tobramycin inhalation solution. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with tobramycin inhalation solution as well as the monitoring required for adverse events and long-term efficacy, approval requires tobramycin inhalation solution to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of tobramycin inhalation solution is recommended in those who meet one of the following:

FDA-Approved Indication

7. **Cystic Fibrosis.** Approve for 1 year if the patient meets BOTH of the following (A and B):
 - A) Patient has *Pseudomonas aeruginosa* in culture of the airway; AND
Note: Examples of culture of the airway include sputum culture, oropharyngeal culture, bronchoalveolar lavage culture.
 - B) The medication is prescribed by or in consultation with a pulmonologist or a physician who specializes in the treatment of cystic fibrosis.

Other Uses with Supportive Evidence

8. **Bronchiectasis, Non-Cystic Fibrosis.** Approve for 1 year if the patient meets ALL of the following (A, B, and C):
 - A) Patient is ≥ 18 years of age; AND
 - B) Patient has *Pseudomonas aeruginosa* in culture of the airway; AND
Note: Examples of culture of the airway include sputum culture, oropharyngeal culture, bronchoalveolar lavage culture.
 - C) The medication is prescribed by or in consultation with a pulmonologist.
9. **Continuation of Tobramycin Inhalation Solution Therapy.** Approve for 1 month if the patient was started on tobramycin inhalation solution and is continuing a course of therapy.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of tobramycin inhalation solution is not recommended in the following situations:

12. **Nasal Rinse.** Tobramycin inhalation solution is not approvable for compounding of tobramycin nasal rinse.
13. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Antibiotics (Injectable) Prior Authorization Policy

REVIEW DATE: 10/09/2024

Note: This list is not all-inclusive.

OVERVIEW

Injectable antibiotics are used to treat moderate to severe bacterial infections.¹ In addition, injectable antibiotics can be used for prophylactic indications (e.g., before surgeries; in immunocompromised patients [e.g., patients with cancer]).

Recently, some injectable antibiotics are being used with nasal or nebulized corticosteroids to compound nasal rinses and nasal irrigations. There are no data to support the use of these products in this manner.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of the injectable antibiotics listed above, when these products are prescribed in conjunction with nasal or nebulized dosage forms of beclomethasone, budesonide, ciclesonide, flunisolide, fluticasone, mometasone, or triamcinolone. The list of injectable antibiotics in this policy is not inclusive; other injectable antibiotics may also be targeted in this policy. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days.

Automation: This Prior Authorization policy will apply to injectable antibiotics when there is a prescription history of a nasal or nebulized formulation of the selected corticosteroid (beclomethasone, budesonide, ciclesonide, flunisolide, fluticasone, mometasone, triamcinolone) in the past 180 days. Prescriptions for injectable antibiotics without a claims for nasal or nebulized corticosteroids in the past 180 days are excluded from the Prior Authorization policy.

10/09/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of injectable antibiotics is recommended in those who meet the following criteria:

FDA-Approved Indication

- 1. Systemic Bacterial Infections (Prophylaxis or Treatment).** Approve for 3 months.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of injectable antibiotics is not recommended in the following situations:

- 12.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Antibiotics – Linezolid (Zyvox), Sivextro Prior Authorization Policy

- Zyvox® (linezolid tablets and oral suspension – Pfizer, generic)
- Sivextro™ (tedizolid phosphate tablets – Cubist Pharmaceuticals)

REVIEW DATE: 12/18/2024

OVERVIEW

Linezolid (Zyvox) and Sivextro are synthetic oxazolidinone antimicrobial agents.^{1,2} Both agents have clinical utility in the treatment of infections caused by aerobic Gram-positive bacteria. Cross-resistance between linezolid or Sivextro and other classes of antibiotics is unlikely because the mechanism of action for both of these agents differs from that of other antibacterial agents.

Linezolid is indicated in adults and children for the treatment of the following infections caused by susceptible strains of the designated microorganisms:¹

- **Community-acquired pneumonia (CAP)**, caused by *Streptococcus pneumoniae*, including cases with concurrent bacteremia, or *Staphylococcus aureus* (methicillin-susceptible [MSSA] only);
- **Complicated skin and skin structure infections (SSTIs)**, including diabetic foot infections, without concomitant osteomyelitis caused by *S. aureus* (MSSA and methicillin-resistant [MRSA]), *Streptococcus pyogenes*, or *Streptococcus agalactiae*. Linezolid has not been studied in the treatment of decubitus ulcers;
- **Nosocomial pneumonia**, caused by *S. aureus* (MSSA and MRSA) or *S. pneumoniae*;
- **Uncomplicated SSTIs**, caused by *S. aureus* (MSSA only) or *S. pyogenes*;
- **Vancomycin-resistant *Enterococcus faecium* infections**, including cases with concurrent bacteremia.

Limitation of Use: Linezolid is not indicated for the treatment of Gram-negative infections. It is crucial that specific Gram-negative therapy be initiated immediately if a concomitant Gram-negative pathogen is documented or suspected. The safety and efficacy of linezolid given longer than 28 days have not been evaluated in controlled clinical trials.

Sivextro is indicated for the treatment of **acute bacterial skin and skin structure infections (ABSSSI)** that are caused by susceptible isolates of the following Gram-positive microorganisms: *S. aureus* (MRSA and MSSA), *S. pyogenes*, *S. agalactiae*, *Streptococcus anginosus* Group (including *S. anginosus*, *Streptococcus intermedius*, and *Streptococcus constellatus*), and *Enterococcus faecalis* in adults and pediatric patients ≥ 12 years of age.²

Although linezolid and Sivextro are indicated for the treatment of infections caused by susceptible strains of MSSA and drug-resistant strains of *S. pneumoniae* in some situations, these agents are not the optimal drug or drugs of first-choice for these microorganisms.^{3,4} Other antibiotics may be used. In efforts to reduce the development of drug-resistant bacteria and maintain effectiveness of linezolid and Sivextro, both antibiotics should be used only to treat infections that are proven or strongly suspected to be caused by susceptible bacteria.^{1,2} When culture and susceptibility information are available, they should be considered in selecting or modifying antibacterial therapy. In the absence of such data, local epidemiology and susceptibility patterns may contribute to the empiric selection of therapy.

Guidelines

12/18/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Linezolid and Sivextro are addressed in a number of guidelines from the Infectious Diseases Society of America (IDSA):

- **Diabetic Foot Infections:** A clinical practice guideline for the diagnosis and treatment of diabetic foot infections (2023) notes that diabetic foot infections of moderate severity may be treated with oral or initial parenteral therapy, whereas severe infections should be treated with parenteral therapy.⁶ Linezolid, Cubicin® (daptomycin injection), doxycycline, clindamycin, fluoroquinolones and intravenous (IV) vancomycin are listed as therapy options for infections caused by MRSA.
- **Infective Endocarditis:** Treatment guidelines, from the American Heart Association and endorsed by IDSA (2015), recommend linezolid as a treatment option for patients with infective endocarditis caused by *Enterococcus* species that is resistant to penicillin, aminoglycosides, and vancomycin.⁹
- **MRSA:** Guidelines (2011) for the treatment of MRSA infections recognize linezolid as a treatment option for infections, including those involving the central nervous system (e.g., meningitis, brain abscess), osteomyelitis, and septic arthritis.⁵
- **Multidrug-Resistant Tuberculosis:** Treatment guidelines from the World Health Organization (2022) recommend linezolid to be used in combination with Pretomanid and Sirturo (bedaquiline tablets) for 6 to 9 months for the treatment of multidrug-resistant tuberculosis or rifampin-resistant tuberculosis.¹⁰
- **Pneumonia:** Guidelines from the American Thoracic Society (ATS) and IDSA (2016) recommend that MRSA hospital-acquired pneumonia (HAP) or ventilator-associated pneumonia (VAP) be treated with either vancomycin or linezolid rather than other antibiotics or other antibiotic combinations.⁴ The choice between vancomycin and linezolid may be guided by patient-specific factors such as blood cell counts, concurrent prescriptions for serotonin reuptake inhibitors, renal function, and cost. The available evidence indicates that vancomycin and linezolid are roughly similar and no alternative agent or regimen is clearly superior to these two products. Guidelines from IDSA/ATS (2019) for CAP recommend vancomycin or linezolid for the treatment of community-acquired MRSA.³ In addition, the Pediatric Infectious Diseases Society and IDSA guidelines (2011) for the treatment of CAP in infants and children > 3 months of age recommend linezolid as an alternative to vancomycin for treatment of MRSA, and as an alternative to ceftriaxone for the treatment of *S. pneumoniae* resistant to penicillin.⁸
- **SSTIs:** Guidelines (2014) for the diagnosis and management of SSTIs recommend oral antibiotics such as penicillin VK, cephalosporin, dicloxacillin, and clindamycin for mild nonpurulent (i.e., necrotizing infection, cellulitis, erysipelas) SSTIs.⁷ For moderate nonpurulent SSTI, IV antibiotics such as penicillin, ceftriaxone, cefazolin, and clindamycin are recommended. For moderate purulent SSTIs, empiric treatment can be started with trimethoprim/sulfamethoxazole (TMP/SMX) or doxycycline. For MRSA infections, TMP/SMX is the recommended therapy. Cephalexin or dicloxacillin are usually effective for MSSA infections. For severe purulent SSTI, empiric therapy with IV vancomycin, Cubicin, linezolid, Vibativ® (telavancin intravenous infusion), or Teflaro® (ceftaroline intravenous infusion) are recommended. All of these agents are active against MRSA strains. For severe purulent SSTIs caused by MSSA, therapy can be switched to nafcillin, cefazolin, or clindamycin.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of linezolid and Sivextro. All approvals are provided for the duration noted below. In cases where approval is authorized in months, 1 month is equal to 30 days.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

I. Coverage of linezolid is recommended in those who meet one of the following criteria:

FDA-Approved Indications

1. **Methicillin-Resistant *Staphylococcus* Species Infection, Treatment.** Approve for 1 month.
2. **Vancomycin-Resistant *Enterococcus* Species Infection, Treatment.** Approve for 1 month.

Other Uses with Supportive Evidence

3. **Continuation of Linezolid Therapy.** Approve for 1 month in patients who meet ONE of the following (A or B):
 - A) Patient is transitioning from intravenous (IV) linezolid or IV vancomycin to oral linezolid therapy;
OR
 - B) Patient was started on oral linezolid in an inpatient facility and is continuing therapy.
4. **Treatment of an Infection that is Resistant to Other Antibiotics, but the Organism is Sensitive to Linezolid.** Approve for 1 month.
5. **There is Insufficient Information Available to Make a Determination Regarding Coverage and the Prescriber or Representative Cannot be Contacted.** Approve for up to 2 weeks of therapy.

To avoid delays or disruption in therapy for the patient, if there is insufficient information available to make a determination regarding coverage and the prescriber or representative of the prescriber cannot be contacted, approve linezolid for up to 2 weeks.

6. **Tuberculosis.** Approve for 9 months if the patient meets ALL of the following (A, B, and C):
 - A) Patient is ≥ 18 years of age; AND
 - B) Patient meets ONE of the following (i, ii, or iii):
 - i. Patient has extensively drug-resistant tuberculosis; OR
 - ii. Patient has treatment-intolerant tuberculosis; OR
 - iii. Patient has nonresponsive multidrug-resistant tuberculosis; AND
 - C) Linezolid is prescribed in combination with Sirturo (bedaquiline tablets) and Pretomanid tablets.

II. Coverage of Sivextro is recommended in those who meet one of the following criteria:

FDA-Approved Indication

1. **Acute Bacterial Skin and Skin Structure Infections (ABSSSI) Caused by Methicillin-Resistant *Staphylococcus aureus* (MRSA), Selected *Streptococcus* Species (i.e., *Streptococcus pyogenes*, *Streptococcus agalactiae*, *Streptococcus anginosus* Group) and *Enterococcus faecalis*.** Approve for up to 6 days of therapy.

Other Uses with Supportive Evidence

2. **Continuation of Sivextro Therapy in the Outpatient Setting.** Approve for up to 6 days of therapy in patients transitioning from Sivextro IV therapy to oral therapy.

12/18/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

3. There is Insufficient Information Available to Make a Determination Regarding Coverage and the Prescriber or Representative Cannot be Contacted. Approve for up to 6 days of therapy.

To avoid delays or disruption in therapy for the patient, if there is insufficient information available to make a determination regarding coverage and the prescriber or representative of the prescriber cannot be contacted, approve Sivextro. Since the available data for Sivextro only supports up to 6 days of therapy for the ABSSSI indication, we are limiting approval to this duration.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of linezolid and Sivextro is not recommended in the following situations:

13. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria for both linezolid and Sivextro. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Antibiotics – Vancomycin Capsules Prior Authorization Policy

- Vancocin® (vancomycin capsules – Ani Pharmaceuticals, generic)

REVIEW DATE: 08/28/2024

OVERVIEW

Vancomycin capsules, an antimicrobial, are indicated for the following uses:¹

- ***Clostridioides difficile***- (formerly known as *Clostridium difficile*) **associated diarrhea**.
- **Enterocolitis** caused by ***Staphylococcus aureus*** (including methicillin-resistant strains).

The usual duration of therapy for the treatment of *C. difficile*-associated diarrhea in adults is 10 days and for pediatric patients (< 18 years of age), the duration is typically 7 to 10 days.¹ The usual duration of therapy for the treatment of Staphylococcal enterocolitis is 7 to 10 days.

Recently, vancomycin capsules are being used in conjunction with one or more of the following topical products: clindamycin, clotrimazole, ketoconazole, or mupirocin to compound foot baths or other topical products. There are no data to support such use.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of vancomycin capsules when being prescribed in conjunction with one or more of the following: topical clindamycin products, topical clotrimazole products, topical ketoconazole products, and/or topical mupirocin products. All approvals are provided for the duration noted below.

Automation: This Prior Authorization policy will apply to vancomycin capsules when there is a prescription history of topical clindamycin products, topical clotrimazole products, topical ketoconazole products, and/or topical mupirocin products in the past 180 days. Prescriptions for vancomycin capsules without a claim for topical clindamycin, topical clotrimazole, topical ketoconazole, and/or topical mupirocin products in the past 180 days are excluded from the Prior Authorization policy.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of vancomycin capsules is recommended in those who meet one of the following criteria:

FDA-Approved Indications

2. ***Clostridioides Difficile* – Associated Diarrhea.** Approve for 2 weeks.
3. **Enterocolitis – Caused by *Staphylococcus aureus*.** Approve for 2 weeks.

08/28/2024

PRIOR AUTHORIZATION POLICY

POLICY: Antibiotics – Xifaxan Prior Authorization Policy

- Xifaxan® (rifaximin tablets – Salix)

REVIEW DATE: 12/04/2024

OVERVIEW

Xifaxan, a rifamycin antibiotic, is indicated for the following uses:¹

- **Hepatic encephalopathy (HE)**, to reduce the risk of overt disease in adults.
- **Irritable bowel syndrome with diarrhea (IBS-D)**, in adults.
- **Travelers' diarrhea (TD)**, caused by noninvasive *Escherichia coli* in patients ≥ 12 years of age.

Limitations of Use: TD: Xifaxan should not be used in patients with diarrhea complicated by fever or blood in the stool or diarrhea due to pathogens other than *E. coli*.¹

In the trials of Xifaxan for HE, 91% of the patients were using lactulose concomitantly.¹ Due to small sample size, differences in the treatment effect of those patients not using lactulose concomitantly could not be assessed. Data are lacking to support the use of Xifaxan without concomitant use of lactulose.

Guidelines

- **Hepatic Encephalopathy (HE):** The European Association for the Study of the Liver (EASL) guidelines for HE (2022) recommend Xifaxan as an adjunct to lactulose as secondary prophylaxis following ≥ 1 additional episode of overt HE within 6 months of the first episode.² Guidelines also state that in patients with cirrhosis and previous episodes of overt HE, Xifaxan can be considered for prophylaxis of HE prior to non-urgent transjugular intrahepatic portosystemic shunt (TIPS) placement.
- **IBS with Diarrhea (IBS-D):** The American College of Gastroenterology (ACG) guidelines for the management of IBS (2021) suggest use of Xifaxan to reduce the global symptoms of IBS and to reduce bloating in non-constipated IBS patients.³ In addition, the American Gastroenterological Association (AGA) clinical practice guidelines on the pharmacological management of IBS-D (2022) suggest Xifaxan over no drug treatment for patients with IBS-D (conditional recommendation, moderate evidence).⁴ AGA also suggests retreatment with Xifaxan in patients with an initial response to Xifaxan who develop recurrent symptoms.
- **Small Intestine Bacterial Overgrowth (SIBO):** Clinical guidelines from the ACG (2020) and the AGA (2020) list Xifaxan as an option for the treatment of SIBO.^{9,10} ACG also states that the diagnosis of SIBO can be made with breath testing (glucose hydrogen or lactulose hydrogen), or by small bowel aspiration and culture. Of note, in clinical trials, patients were treated with Xifaxan for a 7-day course for SIBO.⁵⁻⁸
- **Travelers' Diarrhea (TD):** The Centers for Disease Control and Prevention (CDC) Yellow Book – Health Information for International Travel (2024) states that Xifaxan may be used for the treatment of moderate, noninvasive TD and may be used for the treatment of severe, non-dysenteric TD.¹¹ In addition, guidelines developed by an expert panel (2017) state that Xifaxan is appropriate for moderate or severe, non-dysenteric TD, and when indicated for the prophylaxis of TD.¹²
- **Pouchitis:** AGA guidelines on the management of pouchitis and inflammatory pouch disorders (2024) suggest using antibiotic therapy for the treatment of infrequent symptoms of pouchitis and list the preferred antibiotics as ciprofloxacin and/or metronidazole with a treatment duration of 2 to 4 weeks. The AGA suggests against the use of antibiotics for primary prevention of pouchitis.

12/04/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Chronic antibiotic-dependent pouchitis (CADP) is defined as recurrent episodes of pouchitis that respond to antibiotic therapy but relapse shortly after stopping antibiotics. The AGA suggests using chronic antibiotic therapy to treat CADP after ruling out alternative etiologies.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Xifaxan. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of chronic antibiotic-dependent pouchitis, approval for this condition requires Xifaxan to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Xifaxan is recommended in those who meet one of the following criteria:

FDA-Approved Indications

- 10. Hepatic Encephalopathy.** Approve Xifaxan 550 mg tablets for 6 months if the patient meets ALL of the following (A, B, and C):
 - A)** Patient is ≥ 18 years of age; AND
 - B)** According to the prescriber, the patient has previously had overt hepatic encephalopathy; AND
 - C)** Patient meets ONE of the following (i or ii):
 - i.** Xifaxan will be used concomitantly with lactulose; OR
 - ii.** According to the prescriber, the patient has a contraindication or significant intolerance to treatment with lactulose.
- 11. Irritable Bowel Syndrome with Diarrhea.** Approve Xifaxan 550 mg tablets for 14 days if the patient is ≥ 18 years of age.
- 12. Travelers' Diarrhea.** Approve Xifaxan 200 mg tablets for 3 days if the patient meets ALL of the following (A, B, and C):
 - A)** Patient is ≥ 12 years of age; AND
 - B)** According to the prescriber, the patient is afebrile; AND
 - C)** According to the prescriber, the patient does not have blood in the stool.

Other Uses with Supportive Evidence

- 4. Small Intestine Bacterial Overgrowth.** Approve Xifaxan (either strength) for 14 days if small intestine bacterial overgrowth is diagnosed by ONE of the following (A, B, or C):
 - A)** Glucose hydrogen breath test; OR
 - B)** Lactulose hydrogen breath test; OR
 - C)** Small bowel aspiration and culture.
- 5. Pouchitis, Chronic Antibiotic-Dependent.** Approve Xifaxan (either strength) for 1 year if the patient meets ALL of the following (A, B, C, D, and E):
 - A)** Patient has recurrent pouchitis; AND

Note: Recurrent pouchitis is typically considered a of ≥ 3 pouchitis episodes within a 12-month period.

B) According to the prescriber, the episodes of pouchitis respond to antibiotic therapy but relapse shortly after antibiotic discontinuation; AND

C) According to the prescriber, alternative causes of recurrent pouchitis have been ruled out; AND

Note: Alternative etiologies of recurrent pouchitis include but are not limited to *Clostridioides difficile* infection of the pouch, mechanical obstructions, pelvic floor dysfunction.

D) Patient has tried long-term antibiotic therapy trials (at least 4 weeks) of BOTH ciprofloxacin and metronidazole for remission maintenance; AND

E) The medication is prescribed by or in consultation with a gastroenterologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Xifaxan is not recommended in the following situations:

14. *Helicobacter pylori* Infection. The ACG guidelines for the treatment of *H. pylori* do not address the use of Xifaxan.¹³ There are limited trials assessing the efficacy of Xifaxan in the treatment of *H. pylori* infection in adults; the available studies are small, of poor quality, and not conducted in the United States. More data are needed to define the place in therapy of rifaximin in the treatment of *H. pylori*.

15. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Anticoagulants – Dabigatran Prior Authorization Policy

- Pradaxa® (dabigatran etexilate mesylate capsules – Boehringer Ingelheim, generic)
- Pradaxa® Oral Pellets (dabigatran etexilate oral pellets – Boehringer Ingelheim)

REVIEW DATE: 01/24/2024

OVERVIEW

Dabigatran capsules (Pradaxa, generic), a direct thrombin inhibitor, is indicated for the following uses:¹

- **Non-valvular atrial fibrillation**, to reduce the risk of stroke and systemic embolism in adults.
- **Prophylaxis of deep vein thrombosis (DVT) and pulmonary embolism (PE)**, in adults who have undergone hip replacement surgery.
- **Treatment of DVT and PE** in adults who have been treated with a parenteral anticoagulant for 5 to 10 days, as well as **reduction in the risk of recurrence of DVT and PE** in patients who have been previously treated.
- **Treatment of venous thromboembolic events (VTE)**, in pediatric patients 8 to < 18 years of age who have been treated with a parenteral anticoagulant for at least 5 days, as well as **to reduce the risk of recurrence of VTE** in pediatric patients 8 to < 18 years of age who have been previously treated.

Pradaxa oral pellets, a direct thrombin inhibitor, is indicated for the following uses:¹⁵

- **VTE**, treatment in pediatric patients 3 months to < 12 years of age who have been treated with a parenteral anticoagulant for at least 5 days, as well as **to reduce the risk of recurrence of VTE** in pediatric patients 3 months to < 12 years of age who have been previously treated.

It is noted in the prescribing information for dabigatran capsules and Pradaxa oral pellets that not all dosage forms are approved for the same indications and age groups.^{1,15} Due to differences in bioavailability, the individual products are not substitutable on a mg-per-mg basis. Dabigatran capsules are available in the following strengths: 75 mg, 110 mg, and 150 mg. Pradaxa oral pellets are available in the following strengths per packet: 20 mg, 30 mg, 40 mg, 50 mg, 110 mg, and 150 mg.

Guidelines

Guidelines are available which support the use of direct oral anticoagulants (DOACs) in their commonly used clinical settings, such as DVT/PE²⁻⁵ and atrial fibrillation^{6,7}. In patients who are eligible for a DOAC, these are generally preferred over vitamin K antagonists (e.g., warfarin). It is noted that in the randomized trials in atrial fibrillation, DOACs were consistently at least non-inferior to warfarin regarding the composite of stroke or systemic embolism and were associated with lower risk of serious bleeding.⁷

Anticoagulants and Coronavirus Disease 2019 (COVID-19)

Several clinical practice guidelines have been published with regard to use of anticoagulant therapy in the management of COVID-19. Per National Institutes of Health treatment guidelines regarding antithrombotic therapy in patients with COVID-19 (updated October 10, 2023), hospitalized patients with COVID-19 should not be routinely discharged from the hospital while on VTE prophylaxis.⁸ For hospitalized patients, anticoagulant or antiplatelet therapy should not be used to prevent arterial thrombosis outside of the usual standard of care for patients without COVID-19. In nonhospitalized patients with COVID-19, it is not recommended to use anticoagulant and antiplatelet therapy for the prevention of VTE or arterial thrombosis, except in a clinical trial. Of note, Xarelto® (rivaroxaban tablets and oral suspension) is FDA-approved for

01/24/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

prophylaxis of VTE in acutely ill medical patients; Eliquis is not indicated in this setting. Other guidelines have similar recommendations.⁹⁻¹¹

Other Uses with Supportive Evidence

Dabigatran has data supporting its use in prophylaxis after knee replacement surgery; these data are limited to adults.¹²⁻¹⁴ Although data are not robust regarding use of DOACs in other off-label thromboembolic-related conditions, American College of Chest Physicians (CHEST) guidelines (2021) suggest anticoagulation for certain patients (e.g., superficial vein thrombosis, antiphospholipid syndrome).² The choice of anticoagulant is often individualized based on patient-specific factors; therefore, for certain patients, DOAC use may be considered in practice. Evidence for DOACs is limited for off-label scenarios; in general, there is more clinical experience with agents such as vitamin K antagonists (e.g., warfarin) and low molecular weight heparin in these settings.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of dabigatran capsules and Pradaxa oral pellets. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

I. Coverage of dabigatran capsules is recommended in those who meet one of the following criteria:

FDA-Approved Indications

- 1. Atrial Fibrillation (or Atrial Flutter).** Approve for 1 year if the patient is ≥ 18 years of age.
- 2. Deep Vein Thrombosis or Pulmonary Embolism, Treatment.** Approve for 1 year if the patient is ≥ 8 years of age.
- 3. Deep Vein Thrombosis or Pulmonary Embolism, To Reduce the Risk of Recurrence.** Approve for 1 year if the patient is ≥ 8 years of age.
- 4. Deep Vein Thrombosis or Pulmonary Embolism in a Patient Undergoing Hip Replacement Surgery, Prophylaxis.** Approve for 60 days if the patient is ≥ 18 years of age.

Other Uses with Supportive Evidence

- 5. Deep Vein Thrombosis in a Patient Undergoing Knee Replacement Surgery, Prophylaxis.** Approve for 60 days if the patient is ≥ 18 years of age.

- 6. Treatment or Prevention of Other Thromboembolic-Related Conditions.** Approve for 6 months if the patient meets both of the following (A and B):

Note: Examples of other thromboembolic-related conditions include superficial vein thrombosis, splanchnic vein thrombosis, hepatic vein thrombosis, or prophylaxis of venous thromboembolism in a high-risk patient.

A) Patient is ≥ 8 years of age; AND

B) Patient meets one of the following (i or ii):

- i.** Patient has tried warfarin, fondaparinux, or a low molecular weight heparin product (e.g., enoxaparin, Fragmin [dalteparin injection]); OR

Note: A patient who has tried Eliquis (apixaban tablets), Xarelto (rivaroxaban tablets), or Savaysa (edoxaban tablets) is not required to try warfarin, fondaparinux, or a low molecular weight heparin product.

- ii.** Patient has been started on dabigatran capsules for the treatment of an acute thromboembolic condition.

- II.** Coverage of Pradaxa oral pellets is recommended in those who meet one of the following criteria:

FDA-Approved Indications

- 1. Venous Thromboembolic Events, Treatment.** Approve for 1 year if the patient is ≥ 3 months to < 12 years of age.

Note: Examples of venous thromboembolic events include deep vein thrombosis, cerebral venous thrombosis or sinus thrombosis, pulmonary embolism, and central-venous thrombosis.

- 2. Venous Thromboembolic Events, To Reduce the Risk of Recurrence.** Approve for 1 year if the patient is ≥ 3 months to < 12 years of age.

Note: Examples of venous thromboembolic events include deep vein thrombosis, cerebral venous thrombosis or sinus thrombosis, pulmonary embolism, and central-venous thrombosis.

Other Uses with Supportive Evidence

- 3. Treatment or Prevention of Other Thromboembolic-Related Conditions.** Approve for 6 months if the patient meets both of the following (A and B):

Note: Examples of other thromboembolic-related conditions include superficial vein thrombosis, splanchnic vein thrombosis, hepatic vein thrombosis, or prophylaxis of venous thromboembolism in a high-risk patient.

A) Patient is ≥ 3 months to < 12 years of age; AND

B) Patient meets one of the following (i or ii):

- i.** Patient has tried warfarin, fondaparinux, or a low molecular weight heparin product (e.g., enoxaparin, Fragmin [dalteparin injection]); OR

Note: A patient who has tried Eliquis (apixaban tablets), Xarelto (rivaroxaban tablets and oral suspension), or Savaysa (edoxaban tablets) is not required to try warfarin, fondaparinux, or a low molecular weight heparin product.

- ii.** Patient has been started on Pradaxa oral pellets for the treatment of an acute thromboembolic condition.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of dabigatran capsules and Pradaxa oral pellets is not recommended in the following situations:

- 1. Venous Thromboembolism in an Acutely Ill Medical Patient, Prophylaxis.** (Note: This includes post-discharge thromboprophylaxis for a patient hospitalized with coronavirus disease 2019 [COVID-19]). Xarelto is labeled for prophylaxis of venous thromboembolism in acutely ill medical patients and is supported in clinical practice guidelines, including guidelines which address prophylaxis of venous thromboembolism in COVID-19 patients.⁸⁻¹¹
- 15.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Anticoagulants – Eliquis Prior Authorization Policy

- Eliquis® (apixaban tablets – Bristol-Myers Squibb/Pfizer)

REVIEW DATE: 01/24/2024

OVERVIEW

Eliquis, a Factor Xa inhibitor, is indicated for the following uses:¹

- **Non-valvular atrial fibrillation**, to reduce the risk of stroke and systemic embolism.
- **Prophylaxis of deep vein thrombosis (DVT)**, which may lead to pulmonary embolism (PE), in patients who have undergone hip or knee replacement surgery.
- **Treatment of DVT and PE**, as well as **reduction in the risk of recurrence of DVT and PE** following initial therapy.

Safety and effectiveness of Eliquis in pediatric patients have not been established.¹

Guidelines

Guidelines are available which support the use of direct oral anticoagulants (DOACs) in their commonly used clinical settings, such as DVT/PE²⁻⁵ and atrial fibrillation^{6,7}. In patients who are eligible for a DOAC, these are generally preferred over vitamin K antagonists (e.g., warfarin). It is noted that in the randomized trials in atrial fibrillation, DOACs were consistently at least non-inferior to warfarin regarding the composite of stroke or systemic embolism and were associated with lower risk of serious bleeding.⁷

Anticoagulants and Coronavirus Disease 2019 (COVID-19)

Several clinical practice guidelines have been published with regard to use of anticoagulant therapy in the management of COVID-19. Per National Institutes of Health treatment guidelines regarding antithrombotic therapy in patients with COVID-19 (updated October 10, 2023), hospitalized patients with COVID-19 should not be routinely discharged from the hospital while on venous thromboembolism (VTE) prophylaxis.⁸ For hospitalized patients, anticoagulant or antiplatelet therapy should not be used to prevent arterial thrombosis outside of the usual standard of care for patients without COVID-19. In nonhospitalized patients with COVID-19, it is not recommended to use anticoagulant and antiplatelet therapy for the prevention of VTE or arterial thrombosis, except in a clinical trial. Of note, Xarelto® (rivaroxaban tablets and oral suspension) is FDA-approved for prophylaxis of VTE in acutely ill medical patients; Eliquis is not indicated in this setting. Other guidelines have similar recommendations.⁹⁻¹¹

Other Uses with Supportive Evidence

Although data are not robust regarding use of DOACs in other off-label thromboembolic-related conditions, American College of Chest Physicians (CHEST) guidelines (2021) suggest anticoagulation for certain patients (e.g., superficial vein thrombosis, antiphospholipid syndrome).² The choice of anticoagulant is often individualized based on patient-specific factors; therefore, for certain patients, DOAC use may be considered in practice. Evidence for DOACs is limited for off-label scenarios; in general, there is more clinical experience with agents such as vitamin K antagonists (e.g., warfarin) and low molecular weight heparin in these settings.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Eliquis. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Eliquis is recommended in those who meet one of the following criteria:

FDA-Approved Indications

7. **Atrial Fibrillation (or Atrial Flutter).** Approve for 1 year if the patient is ≥ 18 years of age.
8. **Deep Vein Thrombosis in a Patient Undergoing Hip or Knee Replacement Surgery, Prophylaxis.** Approve for 60 days if the patient is ≥ 18 years of age.
9. **Deep Vein Thrombosis or Pulmonary Embolism, Treatment.** Approve for 1 year if the patient is ≥ 18 years of age.
10. **Deep Vein Thrombosis or Pulmonary Embolism to Reduce the Risk of Recurrence.** Approve for 1 year if the patient is ≥ 18 years of age.

Other Uses with Supportive Evidence

11. **Treatment or Prevention of Other Thromboembolic-Related Conditions.** Approve for 6 months if the patient meets both of the following (A and B):
Note: Examples of other thromboembolic-related conditions include superficial vein thrombosis, splanchnic vein thrombosis, hepatic vein thrombosis, or prophylaxis of venous thromboembolism in a high-risk patient.
C) Patient is ≥ 18 years of age; AND
D) Patient meets one of the following (i or ii):
 - i. Patient has tried warfarin, fondaparinux injection, or a low molecular weight heparin product (e.g., enoxaparin injection, Fragmin [dalteparin injection]); OR
Note: A patient who has tried Xarelto (rivaroxaban tablets and oral suspension), Pradaxa (dabigatran capsules), or Savaysa (edoxaban tablets) is not required to try warfarin, fondaparinux, or a low molecular weight heparin product.
 - ii. Patient has been started on Eliquis for the treatment of an acute thromboembolic condition.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Eliquis is not recommended in the following situations:

2. **Venous Thromboembolism in an Acutely Ill Medical Patient, Prophylaxis.** (Note: This includes post-discharge thromboprophylaxis for a patient hospitalized with coronavirus disease 2019 [COVID-19]). Eliquis has been compared with enoxaparin for post-discharge prophylaxis in acutely ill medical patients; however, superiority vs. enoxaparin was not achieved, and bleeding was increased with Eliquis.¹² Xarelto is labeled for prophylaxis of venous thromboembolism in acutely ill medical patients

and is supported in clinical practice guidelines, including guidelines which address prophylaxis of venous thromboembolism in COVID-19 patients.⁸⁻¹¹

3. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Anticoagulants – Savaysa Prior Authorization Policy

- Savaysa® (edoxaban tablets – Daiichi Sankyo)

REVIEW DATE: 01/24/2024

OVERVIEW

Savaysa, a Factor Xa inhibitor, is indicated for the following uses:¹

- **Non-valvular atrial fibrillation**, to reduce the risk of stroke and systemic embolism.
- **Treatment of deep vein thrombosis (DVT) and pulmonary embolism (PE)**, following 5 to 10 days of initial therapy with a parenteral anticoagulant.

Savaysa has a unique Boxed Warning regarding reduced efficacy in non-valvular atrial fibrillation in patients with a creatinine clearance > 95 mL/min; Savaysa should be avoided in these individuals.¹ Safety and effectiveness of Savaysa in pediatric patients have not been established.

Guidelines

Guidelines are available which support the use of direct oral anticoagulants (DOACs) in their commonly used clinical settings, such as DVT/PE²⁻⁵ and atrial fibrillation^{6,7}. In patients who are eligible for a DOAC, these are generally preferred over vitamin K antagonists (e.g., warfarin). It is noted that in the randomized trials in atrial fibrillation, DOACs were consistently at least non-inferior to warfarin regarding the composite of stroke or systemic embolism and were associated with lower risk of serious bleeding.⁷

Anticoagulants and Coronavirus Disease 2019 (COVID-19)

Several clinical practice guidelines have been published with regard to use of anticoagulant therapy in the management of COVID-19. Per National Institutes of Health treatment guidelines regarding antithrombotic therapy in patients with COVID-19 (updated October 10, 2023), hospitalized patients with COVID-19 should not be routinely discharged from the hospital while on venous thromboembolism (VTE) prophylaxis.⁸ For hospitalized patients, anticoagulant or antiplatelet therapy should not be used to prevent arterial thrombosis outside of the usual standard of care for patients without COVID-19. In nonhospitalized patients with COVID-19, it is not recommended to use anticoagulant and antiplatelet therapy for the prevention of VTE or arterial thrombosis, except in a clinical trials. Of note, Xarelto® (rivaroxaban tablets and oral suspension) is FDA-approved for prophylaxis of VTE in acutely ill medical patients; Eliquis is not indicated in this setting. Other guidelines have similar recommendations.⁹⁻¹¹

Other Uses with Supportive Evidence

Savaysa has data for prophylaxis of VTE after hip replacement surgery.¹² Although data are not robust regarding use of DOACs in other off-label thromboembolic-related conditions, American College of Chest Physicians (CHEST) guidelines (2021) suggest anticoagulation for certain patients (e.g., superficial vein thrombosis, antiphospholipid syndrome).² The choice of anticoagulant is often individualized based on patient-specific factors; therefore, for certain patients, DOAC use may be considered in practice. Evidence for DOACs is limited for off-label scenarios; in general, there is more clinical experience with agents such as vitamin K antagonists (e.g., warfarin) and low molecular weight heparin in these settings.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Savaysa. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Savaysa is recommended in those who meet one of the following criteria:

FDA-Approved Indications

12. Atrial Fibrillation (or Atrial Flutter). Approve for 1 year if the patient meets both of the following (A and B):

A) Patient is ≥ 18 years of age; AND

B) Patient has an estimated creatinine clearance ≤ 95 mL/min.

13. Deep Vein Thrombosis or Pulmonary Embolism, Treatment. Approve for 1 year if the patient is ≥ 18 years of age.

Other Uses with Supportive Evidence

14. Deep Vein Thrombosis in a Patient Undergoing Hip Replacement Surgery, Prophylaxis. Approve for 60 days if the patient is ≥ 18 years of age.

15. Treatment or Prevention of Other Thromboembolic-Related Conditions. Approve for 6 months if the patient meets both of the following (A and B):

Note: Examples of other thromboembolic-related conditions include superficial vein thrombosis, splanchnic vein thrombosis, hepatic vein thrombosis, or prophylaxis of venous thromboembolism in a high-risk patient.

E) Patient is ≥ 18 years of age; AND

F) Patient meets one of the following (i or ii):

i. Patient has tried warfarin, fondaparinux, or a low molecular weight heparin product (e.g., enoxaparin, Fragmin [dalteparin injection]); OR

Note: A patient who has tried Eliquis (apixaban tablets), Xarelto (rivaroxaban tablets and oral suspension), or Pradaxa (dabigatran capsules) is not required to try warfarin, fondaparinux, or a low molecular weight heparin.

ii. Patient has been started on Savaysa for the treatment of an acute thromboembolic condition.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Savaysa is not recommended in the following situations:

16. Venous Thromboembolism in an Acutely Ill Medical Patient, Prophylaxis. (Note: This includes post-discharge thromboprophylaxis for a patient hospitalized with coronavirus disease 2019 [COVID-19]). Xarelto is labeled for prophylaxis of venous thromboembolism in acutely ill medical patients and is supported in clinical practice guidelines, including guidelines which address prophylaxis of venous thromboembolism in COVID-19 patients.⁷⁻⁹

17. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Anticoagulants – Xarelto Prior Authorization Policy

- Xarelto® (rivaroxaban tablets and oral suspension – Janssen)

REVIEW DATE: 01/24/2024

OVERVIEW

Xarelto, an oral Factor Xa inhibitor, is indicated for the following uses:¹

- **Atrial fibrillation**, non-valvular, to reduce the risk of stroke and systemic embolism in adults.
- **Coronary artery disease**, in combination with aspirin, to reduce the risk of major adverse cardiovascular events in adults.
- **Prophylaxis of deep vein thrombosis (DVT)**, which may lead to pulmonary embolism (PE), in patients undergoing knee or hip replacement surgery in adults.
- **Prophylaxis of venous thromboembolism in acutely ill medical patients**, in adults at risk for thromboembolic complications not at high risk of bleeding.
- **Peripheral artery disease**, in adults, including patients after recent lower extremity revascularization due to symptomatic peripheral artery disease, in combination with aspirin to reduce the risk of major thrombotic vascular events.
- **Treatment of DVT and PE**, as well as **reduction in the risk of recurrence of DVT and/or PE** in patients at continued risk for recurrent DVT and/or PE after completion of initial treatment. These indications includes patients from birth to < 18 years of age as well as adults.
- **Thromboprophylaxis in a patient with congenital heart disease after the Fontan procedure**, in pediatric patients ≥ 2 years of age.

Dosing and Administration

In the prescribing information for Xarelto tablets and oral suspension, it is noted that for adults who are unable to swallow whole tablets, Xarelto tablets (all strengths) may be crushed and mixed with applesauce immediately prior to use and administered orally.¹ Xarelto tablets (all strengths) may be crushed and suspended in water for administration via nasogastric or gastric tube. Xarelto oral suspension may also be given through nasogastric or gastric tube.

For pediatric patients, tablets must not be split in an attempt to provide a fraction of a tablet dose. For treatment of venous thromboembolism (VTE) and reduction in risk of VTE recurrence in pediatric patients, it is noted that oral suspension or tablets may be used for a patient weighing ≥ 30 kg; for patients weighing < 30 kg, oral suspension should be used. For thromboprophylaxis in pediatric patients with congenital heart disease after the Fontan procedure, oral suspension or tablets may be used for a patient weighing ≥ 50 kg; oral suspension is needed for a patient weighing < 50 kg. It is noted that there are no safety, efficacy, pharmacokinetic, and pharmacodynamic data to support the use of Xarelto 2.5 mg tablets in pediatric patients; therefore, Xarelto 2.5 mg tablets are not recommended in pediatric patients.

Guidelines

Guidelines are available which support the use of direct oral anticoagulants (DOACs) in their commonly used clinical settings, such as DVT/PE²⁻⁵ and atrial fibrillation.^{6,7} In patients who are eligible for a DOAC, these are generally preferred over vitamin K antagonists (e.g., warfarin). It is noted that in the randomized trials in atrial fibrillation, DOACs were consistently at least non-inferior to warfarin regarding the composite of stroke or systemic embolism and were associated with lower risk of serious bleeding.⁷ Guidelines from the Canadian Cardiovascular Society for peripheral arterial disease (2022) recommend

Xarelto in combination with aspirin in selected patients with peripheral arterial disease (high risk of ischemic events).⁸

Anticoagulants and Coronavirus Disease 2019 (COVID-19)

Several clinical practice guidelines have been published with regard to use of anticoagulant therapy in the management of COVID-19. Per National Institutes of Health treatment guidelines regarding antithrombotic therapy in patients with COVID-19 (updated October 10, 2023), hospitalized patients with COVID-19 should not be routinely discharged from the hospital while on venous thromboembolism (VTE) prophylaxis.⁹ For hospitalized patients, anticoagulant or antiplatelet therapy should not be used to prevent arterial thrombosis outside of the usual standard of care for patients without COVID-19. In nonhospitalized patients with COVID-19, it is not recommended to use anticoagulant and antiplatelet therapy for the prevention of VTE or arterial thrombosis, except in a clinical trials. Of note, Xarelto® (rivaroxaban tablets and oral suspension) is FDA-approved for prophylaxis of VTE in acutely ill medical patients; Eliquis is not indicated in this setting. Other guidelines have similar recommendations.¹⁰⁻¹²

Other Uses with Supportive Evidence

Although data are not robust regarding use of DOACs in other off-label thromboembolic-related conditions, American College of Chest Physicians (CHEST) guidelines (2021) suggest anticoagulation for certain patients (e.g., superficial vein thrombosis, antiphospholipid syndrome).² The choice of anticoagulant is often individualized based on patient-specific factors; therefore, for certain patients, DOAC use may be considered in practice. Evidence for DOACs is limited for off-label scenarios; in general, there is more clinical experience with agents such as vitamin K antagonists (e.g., warfarin) and low molecular weight heparin in these settings.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Xarelto. All approvals are provided for the approval duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Xarelto (tablets and oral suspension) is recommended in those who meet one of the following criteria:

FDA-Approved Indications

1. **Atrial Fibrillation (or Atrial Flutter).** Approve for 1 year if the patient meets both of the following (A and B):
 1. Patient is ≥ 18 years of age; AND
 1. If Xarelto oral suspension is being requested, approve if the patient is unable to have Xarelto tablets appropriately administered.
2. **Coronary Artery Disease.** Approve for 1 year if the patient meets all of the following (A, B, and C):
 - A) Patient is ≥ 18 years of age; AND
 - B) Patient will be taking concomitant aspirin at least 75 mg daily; AND
 1. If Xarelto oral suspension is being requested, approve if the patient is unable to have Xarelto tablets appropriately administered.

01/24/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

3. **Deep Vein Thrombosis in a Patient Undergoing Knee or Hip Replacement Surgery, Prophylaxis.** Approve for 60 days if the patient meets both of the following (A and B):
- A) Patient is ≥ 18 years of age; AND
 - B) If Xarelto oral suspension is being requested, approve if the patient is unable to have Xarelto tablets appropriately administered.
4. **Deep Vein Thrombosis or Pulmonary Embolism, Treatment.** Approve for 1 year if the patient meets one of the following (A or B):
- A) Xarelto tablets: Approve.
 - B) Xarelto oral suspension: Approve if the patient meets one of the following (i or ii):
 - i. Patient is unable to have Xarelto tablets appropriately administered; OR
 - ii. The prescribed Xarelto dose cannot be achieved by Xarelto 10 mg, 15 mg, or 20 mg tablets.
5. **Deep Vein Thrombosis or Pulmonary Embolism, to Reduce the Risk of Recurrence.** Approve for 1 year if the patient meets one of the following (A or B):
- A) Xarelto tablets: Approve.
 - B) Xarelto oral suspension: Approve if the patient meets one of the following (i or ii):
 - i. Patient is unable to have Xarelto tablets appropriately administered; OR
 - ii. The prescribed Xarelto dose cannot be achieved by Xarelto 10 mg, 15 mg, or 20 mg tablets.
6. **Peripheral Artery Disease.** Approve for 1 year if the patient meets all of the following (A, B, and C):
- A) Patient is ≥ 18 years of age; AND
 - B) Patient will be taking concomitant aspirin at least 75 mg daily; AND
 - C) If Xarelto oral suspension is being requested, patient is unable to have Xarelto tablets appropriately administered.
7. **Thromboprophylaxis in a Patient with Congenital Heart Disease.** Approve for 1 year if the patient meets all of the following (A, B, and C):
- A) Patient is ≥ 2 years of age and < 18 years of age; AND
 - B) Patient has undergone the Fontan procedure; AND
 - C) If Xarelto oral suspension is being requested, patient meets one of the following (i or ii):
 - i. Patient is unable to have Xarelto tablets appropriately administered; OR
 - ii. The prescribed Xarelto dose cannot be achieved by Xarelto 10 mg, 15 mg, or 20 mg tablets.
8. **Venous Thromboembolism in an Acutely Ill Medical Patient, Prophylaxis.** Approve for 60 days if the patient meets both of the following (A and B):
- Note: This includes post-discharge thromboprophylaxis for a patient hospitalized with coronavirus disease 2019 (COVID-19).
- A) Patient is ≥ 18 years of age; AND
 - B) If Xarelto oral suspension is being requested, patient is unable to have Xarelto tablets appropriately administered.

Other Uses with Supportive Evidence

9. **Treatment or Prevention of Other Thromboembolic-Related Conditions.** Approve for 6 months if the patient meets both of the following (A and B):
- Note: Examples of other thromboembolic-related conditions include superficial vein thrombosis, splanchnic vein thrombosis, hepatic vein thrombosis, or prophylaxis of venous thromboembolism in a high-risk patient.

- A)** Patient meets one of the following (i or ii):
- i.** Patient has tried warfarin, fondaparinux or a low molecular weight heparin product (e.g., enoxaparin, Fragmin [dalteparin injection]); OR
Note: A patient who has tried Eliquis (apixaban tablets), Pradaxa (dabigatran capsules and oral pellets), or Savaysa (edoxaban tablets) is not required to try warfarin, fondaparinux, or a low molecular weight heparin.
 - ii.** Patient has been started on Xarelto for the treatment of an acute thromboembolic condition;
AND
- B)** If Xarelto oral suspension is being requested, approve if the patient meets one of the following (i or ii):
- i.** Patient is unable to have Xarelto tablets appropriately administered; OR
 - ii.** The prescribed Xarelto dose cannot be achieved by Xarelto 10 mg, 15 mg, or 20 mg tablets.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Xarelto is not recommended in the following situations:

- 4.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Antifungals (Azoles) – Intravenous Products Prior Authorization Policy

- Cresemba® (isavuconazonium sulfate intravenous infusion – Astellas)
- Fluconazole intravenous infusion – generic only
- Noxafil® (posaconazole intravenous infusion – Merck, generic)

Vfend® (voriconazole intravenous infusion – Pfizer, generic)

Review Date: 3/6/2024

Overview

Cresemba intravenous infusion, fluconazole intravenous infusion, posaconazole intravenous infusion, and voriconazole intravenous infusion are azole antifungals. These products are indicated for prophylaxis and/or treatment of systemic fungal infections, including Candida infections, cryptococcal meningitis, esophageal candidiasis, invasive aspergillosis, and invasive mucormycosis.¹⁻⁴ The specific indications are different for the four products; refer to the prescribing information for details.

Injectable formulations of some antifungals have been compounded with other topical products (clindamycin, clotrimazole, ketoconazole, and mupirocin) to make foot baths and other products. There are no data to support these uses.

Policy Statement

Prior Authorization is recommended for prescription benefit coverage of the intravenous formulations of Cresemba, fluconazole, posaconazole, and voriconazole when these products are prescribed in conjunction with select topical products: clindamycin, clotrimazole, ketoconazole, and mupirocin. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days.

Automation: If there are no prescription claims for topical clindamycin, topical clotrimazole, topical ketoconazole, and/or topical mupirocin products in the past 180 days, the Prior Authorization edit will not be applied in adjudication. Prior Authorization will only apply to prescriptions for the intravenous formulations of Cresemba, fluconazole, posaconazole, and voriconazole when there is of topical clindamycin, topical clotrimazole, topical ketoconazole, and/or topical mupirocin products in the past 180 days.

Recommended Authorization Criteria

Coverage of Cresemba, fluconazole, posaconazole, and voriconazole is recommended in those who meet the following criteria:

FDA-Approved Indication

Systemic Fungal Infections (Prophylaxis or Treatment). Approve for 3 months.

03/01/2023

© 2023. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Conditions Not Recommended for Approval

Coverage of Cresemba, fluconazole, posaconazole, and voriconazole is not recommended in the following situations:

Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Antifungals – Cresemba (Oral) Prior Authorization Policy

- Cresemba® (isavuconazonium sulfate capsules – Astellas Pharma)

REVIEW DATE: 07/31/2024

OVERVIEW

Cresemba, an azole antifungal, is indicated in adults and pediatric patients ≥ 6 years of age who weigh ≥ 16 kg for the following uses:¹

- **Invasive aspergillosis.**
- **Invasive mucormycosis.**

Cresemba is also available for use as an intravenous (IV) infusion.¹ Switching between the IV and oral formulation is acceptable as the two formulations are bioequivalent. Patients are typically transitioned from the IV formulation to the oral formulation while in the hospital or upon discharge. In the pivotal study involving patients with invasive aspergillosis, patients were initiated on IV Cresemba before transitioning to oral Cresemba therapy. The mean treatment duration was 47 days, of which patients received IV Cresemba for 8 to 9 days. In an open-label, non-comparative study that included a subset of patients with invasive mucormycosis, patients were treated with either IV or oral Cresemba. The median duration of Cresemba therapy was 102 days for patients classified as primary, 33 days for refractory, and 85 days for intolerant.

Guidelines/Recommendations

The Infectious Diseases Society of America (IDSA) [2016] recommends Cresemba as a treatment option for invasive aspergillosis and different invasive syndromes of *Aspergillus* (e.g., invasive pulmonary aspergillosis, invasive sinus aspergillosis, aspergillosis of the central nervous system).² Treatment of invasive aspergillosis should be continued for a minimum of 6 to 12 weeks, depending on the degree and duration of immunosuppression, site of disease, and evidence of disease improvement.

Other Uses with Supportive Evidence

The National Comprehensive Cancer Network (NCCN) Guidelines for Prevention and Treatment of Cancer-Related Infections (version 1.2024 – April 30, 2024) note that use of Cresemba may be considered for patients who have invasive or refractory aspergillosis or mucormycosis or who have intolerance to amphotericin B formulations.³ NCCN also notes Cresemba as a treatment option for the prevention of fungal infections in patients with significant graft-versus-host disease (GVHD) [especially grade 3/4] who are receiving immunosuppressive therapy; treatment should continue until resolution of significant GVHD. Cresemba is also a treatment option for these groups of patients with neutropenia: patients with myelodysplastic syndrome, patients with acute myeloid leukemia, and patients who are allogeneic hematopoietic cell transplant recipients; treatment should continue until resolution of neutropenia.

The guidelines for prevention and treatment of opportunistic infections in adults and adolescents with human immunodeficiency virus (HIV) infections (last updated July 2024) note Cresemba as a treatment option for patients with HIV and esophageal candidiasis.⁴

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Cresemba capsules. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Cresemba capsules is recommended in those who meet one of the following criteria:

FDA-Approved Indications

1. **Aspergillus Infection – Treatment.** Approve for 3 months.
2. **Mucormycosis – Treatment.** Approve for 3 months.

Other Uses with Supportive Evidence

3. **Candidiasis (Systemic) in a Patient with Human Immunodeficiency Virus (HIV) Infection – Treatment.** Approve for 3 months.
4. **Fungal Infection (Systemic) in a Patient With Cancer and Neutropenia – Prophylaxis.** Approve for 6 months.
Note: Examples of cancers predisposing neutropenic patients to risk of fungal infections include: myelodysplastic syndrome, acute myeloid leukemia, patients post-allogeneic hematopoietic cell transplant.
5. **Fungal Infection (Systemic) in a Patient with Graft-versus-Host Disease – Prophylaxis.** Approve for 6 months.
6. **Fungal Infection (Systemic) That Is Susceptible to Cresemba – Treatment.** Approve for 3 months.
7. **Patient is Currently Receiving Cresemba.** Approve for 3 months to complete the course of therapy.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Cresemba capsules is not recommended in the following situations:

18. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Antifungals – Flucytosine Prior Authorization Policy

- Ancobon® (flucytosine capsules – Bausch Health, generic)

REVIEW DATE: 05/29/2024

OVERVIEW

Flucytosine, an antifungal, is indicated for the treatment of serious infections caused by susceptible strains of *Candida* and/or *Cryptococcus*:¹

- ***Candida* infections:** Septicemia, endocarditis, and urinary system infections have been effectively treated with flucytosine. Limited trials in pulmonary infections justify the use of flucytosine.
- ***Cryptococcus* infections:** Meningitis and pulmonary infections have been treated effectively. Studies in septicemias and urinary tract infections are limited, but good responses have been reported.

Flucytosine should be used in combination with amphotericin B for the treatment of systemic candidiasis and cryptococcosis due to emergence of resistance to flucytosine.

Treatment duration is varied; patients are treated until infection has cleared.²⁻⁴

There have been reports of flucytosine capsules being compounded for use as foot baths. There are no data to support the use of flucytosine capsules in this manner and coverage of flucytosine capsules for this use is not recommended.

Guidelines/Recommendations

Infectious Diseases Society of America (IDSA) guidelines for treatment of *Candida* infections (2016) note that flucytosine can be used as monotherapy or in combination with other antifungals for these infections. The European Confederation of Medical Mycology, the International Society for Human and Animal Mycology, and the American Society of Microbiology developed global guidelines for the diagnosis and management of *Cryptococcosis* (2024) and note that flucytosine should be used in combination with other antifungals for these infections.

Flucytosine capsules may be extemporaneously compounded for vaginal use for patients with vulvovaginal candidiasis.^{2,4} IDSA guidelines for the management of candidiasis (2016) note 17% flucytosine cream to be an option, as monotherapy or in combination with 3% amphotericin B cream, for the treatment of *C. glabrata* vulvovaginitis unresponsive to oral azole antifungals (weak recommendation; low quality evidence); duration of treatment is 14 days.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of flucytosine capsules. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

05/29/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Coverage of flucytosine capsules is recommended in those who meet one of the following criteria:

FDA-Approved Indications

8. ***Candida* Infection (Systemic) – Treatment.** Approve for 3 months.
9. ***Cryptococcus* Infection (Systemic) – Treatment.** Approve for 3 months.

Other Uses with Supportive Evidence

10. **Fungal Infection (Systemic) That Is Susceptible to Flucytosine – Treatment.** Approve for 3 months.
11. **Vulvovaginal candidiasis.** Approve for 14 days if the patient has previously tried at least one other antifungal therapy.
12. **Patient is Currently Receiving Flucytosine For a Systemic Fungal Infection.** Approve for 3 months to complete the course of therapy.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of flucytosine capsules is not recommended in the following situations:

19. **Foot baths.** There are no data to support the use of flucytosine capsules for use as foot baths.
20. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Antifungals – Posaconazole (Oral) Prior Authorization Policy

- Noxafil® (posaconazole delayed-release tablets [generic], oral suspension [generic], PowderMix for delayed-release oral suspension – Merck)

REVIEW DATE: 07/31/2024

OVERVIEW

Posaconazole, an azole antifungal, is indicated for the following uses:¹

- **Prophylaxis of invasive *Aspergillus* and *Candida* infections** in patients who are at high risk of developing these infections due to being severely immunocompromised, such as hematopoietic stem cell transplant (HSCT) recipients with graft-versus-host disease (GVHD) or those with hematologic malignancies with prolonged neutropenia from chemotherapy: delayed-release tablets, in patients ≥ 2 years of age who weigh > 40 kg; oral suspension, in patients ≥ 13 years of age; Noxafil PowderMix for delayed-release oral suspension, in pediatric patients ≥ 2 years of age who weigh < 40 kg.
- **Treatment of invasive aspergillosis** in patients ≥ 13 years of age (delayed-release tablets).
- **Treatment of oropharyngeal candidiasis** including oropharyngeal candidiasis refractory to itraconazole and/or fluconazole, in patients ≥ 13 years of age (oral suspension).

The duration of posaconazole therapy is varied. In a pivotal study, where posaconazole oral suspension was compared with fluconazole capsules as prophylaxis for the prevention of invasive fungal infections in allogeneic HSCT recipients with GVHD, the mean duration of posaconazole therapy was 80 days.¹

Guidelines

The Infectious Diseases Society of America (IDSA) guidelines for aspergillosis (2016) recommend posaconazole for treatment and prophylaxis of invasive aspergillosis.² The IDSA guidelines for candidiasis (2016) and the National Comprehensive Cancer Network (NCCN) Guidelines for the Prevention and Treatment of Cancer-Related Infections (version 1.2024 – April 30, 2024) note posaconazole as one of the drugs of choice for the treatment of fluconazole-refractory oropharyngeal candidiasis.^{3,5} The IDSA notes posaconazole as having high-quality evidence for prophylaxis of candidiasis.

NCCN notes posaconazole is active against *Candida* and *Aspergillus* species, some *Mucorales spp*, some of the rarer molds, and against dimorphic fungi and *C. neoformans*. Posaconazole is noted as a treatment option for the prevention of fungal infections in patients with significant graft-versus-host disease (GVHD) [especially grade 3/4] who are receiving immunosuppressive therapy; treatment should continue until resolution of significant GVHD. Posaconazole is also a treatment option for these groups of patients with neutropenia: patients with myelodysplastic syndrome, patients with acute myeloid leukemia, and patients who are allogeneic hematopoietic cell transplant recipients; treatment should continue until resolution of neutropenia. NCCN also notes posaconazole as a treatment option for the treatment of the following infections: mouth and esophageal infections (e.g., oral thrush) refractory to fluconazole; invasive fusariosis; *Scedosporium* infections; and maintenance treatment of mucormycosis.⁵ In addition, posaconazole is a treatment option for patients with invasive, refractory infections who have intolerance to amphotericin B formulations.

The guidelines for prevention and treatment of opportunistic infections in adults and adolescents with human immunodeficiency virus (HIV) infections (last updated July 2024) note posaconazole as an option

07/31/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

for treatment of patients with coccidioidomycosis, or histoplasmosis; and as chronic suppressive treatment of esophageal candidiasis.⁴

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Noxafil/posaconazole (oral). All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Noxafil/posaconazole is recommended in those who meet ONE of the following criteria:

FDA-Approved Indications

- 13. *Aspergillus* Infection – Prophylaxis.** Approve for 6 months.
- 14. *Aspergillus* Infection – Treatment.** Approve for 3 months.
- 15. *Candida* Infection (Systemic) – Prophylaxis.** Approve for 6 months.
- 16. Oropharyngeal Candidiasis – Treatment.** Approve for 3 months.

Other Uses with Supportive Evidence

- 17. Esophageal Candidiasis in a Patient with Human Immunodeficiency Virus (HIV) Infection – Chronic Suppressive Treatment.** Approve for 6 months.
- 18. Fungal Infection (Systemic) in a Patient With Cancer and Neutropenia – Prophylaxis.** Approve for 6 months.
Note: Examples of cancers predisposing neutropenic patients to risk of fungal infections include: myelodysplastic syndrome, acute myeloid leukemia, patients post-allogeneic hematopoietic cell transplant.
- 19. Fungal Infection (Systemic) in a Patient with Graft-versus-Host Disease - Prophylaxis.** Approve for 6 months.
- 20. Fungal Infection (Systemic) in a Patient with Human Immunodeficiency Virus (HIV) Infection – Treatment.** Approve for 3 months.
- 21. Fusariosis, Invasive – Treatment.** Approve for 3 months.
- 22. Mouth and Esophageal Infection (Refractory to Other Azole Antifungals) – Treatment.** Approve for 3 months.
- 23. Mucormycosis – Maintenance Treatment.** Approve for 6 months.
- 24. *Scedosporium* Infection – Treatment.** Approve for 3 months.

07/31/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

25. Fungal Infection (Systemic) that is Susceptible to Posaconazole – Treatment. Approve for 3 months.

26. Patient is Currently Receiving Posaconazole. Approve for 3 months to complete the course of therapy.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Noxafil/Posaconazole (oral) is not recommended in the following situations:

21. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION WITH STEP THERAPY POLICY

POLICY: Antifungals – Tolsura Prior Authorization with Step Therapy Policy

- Tolsura® (itraconazole capsules – Mayne Pharma)

REVIEW DATE: 07/31/2024

OVERVIEW

Tolsura, an azole antifungal, is indicated in immunocompromised and non-immunocompromised adults for the following uses:¹

- **Aspergillosis**, pulmonary and extrapulmonary, in patients who are intolerant of or who are refractory to amphotericin B therapy.
- **Blastomycosis**, pulmonary and extrapulmonary.
- **Histoplasmosis**, including chronic cavitary pulmonary disease and disseminated, non-meningeal histoplasmosis.

Limitation of use: Tolsura is not indicated for the treatment of onychomycosis. Tolsura is not interchangeable or substitutable with other itraconazole products due to the differences in the dosing between Tolsura and other itraconazole products.

Tolsura contains itraconazole dispersed in a polymer matrix and encapsulated in a hard gelatin capsule.¹ Compared with conventional itraconazole, Tolsura has improved overall absorption.² Itraconazole capsules (Sporanox®, generic) are also indicated for these uses and for the treatment of onychomycosis in non-immunocompromised patients.³ Itraconazole oral solution (Sporanox®, generic) is indicated for the treatment of oropharyngeal and esophageal candidiasis.⁴ The drug exposure with itraconazole oral solution is greater than that of the capsules when the same dose of drug is given.

Guidelines

The use of Tolsura in the prevention/treatment of systemic fungal infections is not addressed in guidelines.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Tolsura. This Prior Authorization Policy also contains a Step Therapy component. When clinically appropriate, patients are directed to try one Step 1 Product (itraconazole capsules or oral solution) prior to Tolsura (Step 2). All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days.

Automation: None.

07/31/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Tolsura is recommended in those who meet one of the following criteria:

FDA-Approved Indications

4. **Aspergillosis – Pulmonary or Extrapulmonary – Treatment.** Approve for 3 months if the patient meets ONE of the following (A or B):
 - a) Patient has tried one of itraconazole capsules or oral solution; OR
 - b) Patient is currently receiving Tolsura for this condition.
5. **Blastomycosis – Pulmonary or Extrapulmonary – Treatment.** Approve for 3 months if the patient meets ONE of the following (A or B):
 - a) Patient has tried one of itraconazole capsules or oral solution; OR
 - b) Patient is currently receiving Tolsura for this condition.
6. **Histoplasmosis – Including Chronic Cavitary Pulmonary Disease and Disseminated, Non-Meningeal – Treatment.** Approve for 3 months if the patient meets ONE of the following (A or B):
 - a) Patient has tried one of itraconazole capsules or oral solution; OR
 - b) Patient is currently receiving Tolsura for this condition.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Tolsura is not recommended in the following situations:

22. **Onychomycosis.** Tolsura is not indicated for the treatment of onychomycosis (noted as a Limitation of Use in the Tolsura prescribing information).¹
23. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Antifungals – Vivjoa Prior Authorization Policy

- Vivjoa™ (oteseconazole capsules – Mycovia)

REVIEW DATE: 08/28/2024

OVERVIEW

Vivjoa, an azole antifungal, is indicated to reduce the incidence of **recurrent vulvovaginal candidiasis** (RVVC) in females with a history of RVVC who are not of reproductive potential.¹ Females who are NOT of reproductive potential are defined as: persons who are biological females who are postmenopausal or have another reason for permanent infertility (e.g., tubal ligation, hysterectomy, salpingo-oophorectomy). Vivjoa is contraindicated in females of reproductive potential and in pregnant and lactating women.

The Vivjoa pivotal studies enrolled females with RVVC, which was defined as three or more episodes of vulvovaginal candidiasis in a 12-month period; this definition aligns with the Centers for Disease Control and Prevention's (CDC) definition of RVVC.^{1,2}

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Vivjoa. All approvals are provided for 30 days, which is an adequate duration for the patient to receive one course of treatment.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Vivjoa is recommended in those who meet the following criteria:

FDA-Approved Indication

- 6. Recurrent Vulvovaginal Candidiasis.** Approve one course of treatment if the patient meets ALL of the following (A, B, C, D, and E):

A) Patient is ≥ 18 years of age; AND

B) Patient has had at least three episodes of vulvovaginal candidiasis in a 12-month period; AND

Note: A patient who has had two or more previous episodes of vulvovaginal candidiasis in the previous 12 months (prior to the current infection) would meet this requirement.

C) Patient is NOT of reproductive potential; AND

Note: A person who is NOT of reproductive potential is defined as a person who is a biological female who is postmenopausal or has another reason for permanent infertility (e.g., tubal ligation, hysterectomy, salpingo-oophorectomy).

D) Patient is NOT pregnant; AND

E) Patient is NOT breastfeeding.

PRIOR AUTHORIZATION POLICY

POLICY: Antifungals – Voriconazole (Oral) Prior Authorization with Step Therapy Policy

- Vfend® (voriconazole tablets and oral suspension – Roerig/Pfizer, generic)

REVIEW DATE: 07/31/2024

OVERVIEW

Voriconazole, an azole antifungal, is indicated in patients ≥ 2 years of age for the following uses:¹

- **Candidemia**, in non-neutropenic patients and other deep tissue *Candida* infections.
- **Esophageal candidiasis**.
- **Invasive aspergillosis**.
- ***Scedosporium apiospermum*** (asexual form of *Pseudallescheria boydii*) and ***Fusarium spp.*** (including *Fusarium solani*), in patients intolerant of, or refractory to, other therapy.

The duration of voriconazole therapy is varied, ranging from a median duration of 15 days for esophageal candidiasis to 76 days for invasive aspergillosis.¹

Guidelines

The Infectious Diseases Society of America (IDSA) recommends voriconazole as a treatment option for the treatment or prevention of invasive aspergillosis (2016) and for candidemia and candidiasis.^{2,3} Use of voriconazole for treatment of infections caused by *Candida spp* and *Aspergillus spp* are also noted in the National Comprehensive Cancer Network (NCCN) guidelines for the prevention and treatment of cancer-related infections (version 1.2024 – April 30, 2024).⁴ The IDSA guidelines for management of candidiasis note voriconazole has demonstrated effectiveness for candidemia and candidiasis, including mucosal and invasive candidiasis (e.g., *Candida* intravascular infections, including endocarditis and infections of implantable cardiac devices; fluconazole-refractory oropharyngeal candidiasis; *Candida* endophthalmitis).³ Voriconazole represents an option in the first-line treatment of infections due to *Scedosporium spp* and *Fusarium spp*.⁵

NCCN also notes voriconazole as a treatment option for the prevention of fungal infections in patients with significant graft-versus-host disease (GVHD) [especially grade 3/4] who are receiving immunosuppressive therapy; treatment should continue until resolution of significant GVHD.⁴ Voriconazole is also a treatment option for these groups of patients with neutropenia: patients with myelodysplastic syndrome, patients with acute myeloid leukemia, and patients who are allogeneic hematopoietic cell transplant recipients; treatment should continue until resolution of neutropenia.

The IDSA guidelines for the management of blastomycosis (2008; archived) note voriconazole as an option for the treatment of central nervous system blastomycosis.⁶

The Guidelines for Prevention and Treatment of Opportunistic Infections in Adults and Adolescents with Human Immunodeficiency Virus (HIV) Infections (last updated July 2024) recommend voriconazole as a treatment option for the prophylaxis/treatment of various fungal infections (e.g., histoplasmosis, coccidioidomycosis, and talaromycosis) in patients with HIV.⁷

07/31/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Vfend tablets and oral suspension and generic voriconazole tablets and oral suspension. This Prior Authorization Policy also contains a Step Therapy component. When clinically appropriate, patients are directed to try the generic product. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Vfend/Voriconazole is recommended in those who meet one of the following criteria:

FDA-Approved Indications

27. *Aspergillus* Infection – Treatment. Approve for 3 months if the patient meets ONE of the following (A or B):

- A) Generic voriconazole tablets or oral suspension is requested; OR
- B) Patient meets BOTH of the following (i and ii):
 - i. Patient has tried the corresponding generic voriconazole product (tablet or oral suspension); AND
 - ii. Patient cannot take the generic voriconazole product due to a formulation difference in the inactive ingredient(s) [e.g., difference in dyes, fillers, preservatives] between the brand and the bioequivalent generic product, which per the prescriber, would result in a significant allergy or serious adverse reaction.

28. *Candida* (Systemic) Infection – Treatment. Approve for 3 months if the patient meets ONE of the following (A or B):

- A) Generic voriconazole tablets or oral suspension is requested; OR
- B) Patient meets BOTH of the following (i and ii):
 - i. Patient has tried the corresponding generic voriconazole product (tablet or oral suspension); AND
 - ii. Patient cannot take the generic voriconazole product due to a formulation difference in the inactive ingredient(s) [e.g., difference in dyes, fillers, preservatives] between the brand and the bioequivalent generic product, which per the prescriber, would result in a significant allergy or serious adverse reaction.

29. Esophageal Candidiasis – Treatment. Approve for 3 months if the patient meets ONE of the following (A or B):

- A) Generic voriconazole tablets or oral suspension is requested; OR
- B) Patient meets BOTH of the following (i and ii):
 - i. Patient has tried the corresponding generic voriconazole product (tablet or oral suspension); AND
 - ii. Patient cannot take the generic voriconazole product due to a formulation difference in the inactive ingredient(s) [e.g., difference in dyes, fillers, preservatives] between the brand and the bioequivalent generic product, which per the prescriber, would result in a significant allergy or serious adverse reaction.

30. *Fusarium* Infection – Treatment. Approve for 3 months if the patient meets ONE of the following (A or B):

- A) Generic voriconazole tablets or oral suspension is requested; OR
- B) Patient meets BOTH of the following (i and ii):
 - i. Patient has tried the corresponding generic voriconazole product (tablet or oral suspension); AND
 - ii. Patient cannot take the generic voriconazole product due to a formulation difference in the inactive ingredient(s) [e.g., difference in dyes, fillers, preservatives] between the brand and the bioequivalent generic product, which per the prescriber, would result in a significant allergy or serious adverse reaction.

31. *Scedosporium apiospermum* Infection – Treatment. Approve for 3 months if the patient meets ONE of the following (A or B):

- A) Generic voriconazole tablets or oral suspension is requested; OR
- B) Patient meets BOTH of the following (i and ii):
 - i. Patient has tried the corresponding generic voriconazole product (tablet or oral suspension); AND
 - ii. Patient cannot take the generic voriconazole product due to a formulation difference in the inactive ingredient(s) [e.g., difference in dyes, fillers, preservatives] between the brand and the bioequivalent generic product, which per the prescriber, would result in a significant allergy or serious adverse reaction.

Other Uses with Supportive Evidence

32. *Aspergillus* Infection – Prophylaxis. Approve for 6 months if the patient meets ONE of the following (A or B):

- A) Generic voriconazole tablets or oral suspension is requested; OR
- B) Patient meets BOTH of the following (i and ii):
 - i. Patient has tried the corresponding generic voriconazole product (tablet or oral suspension); AND
 - ii. Patient cannot take the generic voriconazole product due to a formulation difference in the inactive ingredient(s) [e.g., difference in dyes, fillers, preservatives] between the brand and the bioequivalent generic product, which per the prescriber, would result in a significant allergy or serious adverse reaction.

33. *Blastomycosis* – Treatment. Approve for 3 months if the patient meets ONE of the following (A or B):

- A) Generic voriconazole tablets or oral suspension is requested; OR
- B) Patient meets BOTH of the following (i and ii):
 - i. Patient has tried the corresponding generic voriconazole product (tablet or oral suspension); AND
 - ii. Patient cannot take the generic voriconazole product due to a formulation difference in the inactive ingredient(s) [e.g., difference in dyes, fillers, preservatives] between the brand and the bioequivalent generic product, which per the prescriber, would result in a significant allergy or serious adverse reaction.

34. *Candida* Endophthalmitis – Treatment. Approve for 3 months if the patient meets ONE of the following (A or B):

- A) Generic voriconazole tablets or oral suspension is requested; OR
- B) Patient meets BOTH of the following (i and ii):

- i. Patient has tried the corresponding generic voriconazole product (tablet or oral suspension);
AND
- ii. Patient cannot take the generic voriconazole product due to a formulation difference in the inactive ingredient(s) [e.g., difference in dyes, fillers, preservatives] between the brand and the bioequivalent generic product, which per the prescriber, would result in a significant allergy or serious adverse reaction.

35. Fungal Infection (Systemic) in a Patient With Cancer and Neutropenia – Prophylaxis. Approve for 6 months if the patient meets ONE of the following (A or B):

Note: Examples of cancers predisposing neutropenic patients to risk of fungal infections include: myelodysplastic syndrome, acute myeloid leukemia, patients post-allogeneic hematopoietic cell transplant

A) Generic voriconazole tablets or oral suspension is requested; OR

B) Patient meets BOTH of the following (i and ii):

- i. Patient has tried the corresponding generic voriconazole product (tablet or oral suspension);
AND
- ii. Patient cannot take the generic voriconazole product due to a formulation difference in the inactive ingredient(s) [e.g., difference in dyes, fillers, preservatives] between the brand and the bioequivalent generic product, which per the prescriber, would result in a significant allergy or serious adverse reaction.

10. Fungal Infection (Systemic) in a Patient with Graft-versus-Host Disease - Prophylaxis. Approve for 6 months if the patient meets ONE of the following (A or B):

A) Generic voriconazole tablets or oral suspension is requested; OR

B) Patient meets BOTH of the following (i and ii):

- i. Patient has tried the corresponding generic voriconazole product (tablet or oral suspension);
AND
- ii. Patient cannot take the generic voriconazole product due to a formulation difference in the inactive ingredient(s) [e.g., difference in dyes, fillers, preservatives] between the brand and the bioequivalent generic product, which per the prescriber, would result in a significant allergy or serious adverse reaction.

11. Fungal Infection (Systemic) in a Patient with Human Immunodeficiency Virus (HIV) – Prophylaxis or Treatment. Approve for 6 months if the patient meets ONE of the following (A or B):

A) Generic voriconazole tablets or oral suspension is requested; OR

B) Patient meets BOTH of the following (i and ii):

- i. Patient has tried the corresponding generic voriconazole product (tablet or oral suspension);
AND
- ii. Patient cannot take the generic voriconazole product due to a formulation difference in the inactive ingredient(s) [e.g., difference in dyes, fillers, preservatives] between the brand and the bioequivalent generic product, which per the prescriber, would result in a significant allergy or serious adverse reaction.

12. Oropharyngeal Candidiasis (Fluconazole-Refractory) – Treatment. Approve for 3 months if the patient meets ONE of the following (A or B):

A) Generic voriconazole tablets or oral suspension is requested; OR

B) Patient meets BOTH of the following (i and ii):

- i. Patient has tried the corresponding generic voriconazole product (tablet or oral suspension);
AND

- ii. Patient cannot take the generic voriconazole product due to a formulation difference in the inactive ingredient(s) [e.g., difference in dyes, fillers, preservatives] between the brand and the bioequivalent generic product, which per the prescriber, would result in a significant allergy or serious adverse reaction.

13. Fungal Infection (Systemic) that is Susceptible to Voriconazole – Treatment. Approve for 3 months if the patient meets ONE of the following (A or B):

A) Generic voriconazole tablets or oral suspension is requested; OR

B) Patient meets BOTH of the following (i and ii):

- i. Patient has tried the corresponding generic voriconazole product (tablet or oral suspension); AND
- ii. Patient cannot take the generic voriconazole product due to a formulation difference in the inactive ingredient(s) [e.g., difference in dyes, fillers, preservatives] between the brand and the bioequivalent generic product, which per the prescriber, would result in a significant allergy or serious adverse reaction.

14. Patient is Currently Receiving Voriconazole. Approve for 3 months to complete the course of therapy if the patient meets ONE of the following (A or B):

A) Generic voriconazole tablets or oral suspension is requested; OR

B) Patient meets BOTH of the following (i and ii):

- i. Patient has tried the corresponding generic voriconazole product (tablet or oral suspension); AND
- ii. Patient cannot take the generic voriconazole product due to a formulation difference in the inactive ingredient(s) [e.g., difference in dyes, fillers, preservatives] between the brand and the bioequivalent generic product, which per the prescriber, would result in a significant allergy or serious adverse reaction.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Vfend/voriconazole is not recommended in the following situations:

- 25. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Antiseizure Medications – Clobazam Products Prior Authorization Policy

- Onfi® (clobazam tablets and oral suspension – Lundbeck, generic)
- Sympazan® (clobazam oral soluble film – Aquestive Therapeutics)

REVIEW DATE: 11/13/2024

OVERVIEW

All forms of clobazam are indicated for the adjunctive treatment of seizures associated with **Lennox-Gastaut syndrome (LGS)** in patients ≥ 2 years of age.^{1,2}

Disease Overview

LGS, a severe epileptic and developmental encephalopathy, is associated with a high rate of morbidity and mortality.^{3,4} LGS most often begins between 3 and 5 years of age and comprises approximately 4% to 10% of childhood epilepsies; the prevalence is 0.26 per 1,000 people.³⁻⁶ Affected children experience several different types of seizures, most commonly atonic seizures (sudden loss of muscle tone and limpness, also called drop seizures) and tonic seizures (increased muscle tone and muscle stiffness).^{3,6} Seizures associated with LGS are usually resistant to treatment.⁶ The three main forms of treatment of LGS are antiseizure medications (ASMs), dietary therapy (typically the ketogenic diet), and device/surgery (e.g., vagus nerve stimulation, corpus callosotomy).⁶ None of the therapies are effective in all cases of LGS and the disorder has proven particularly resistant to most therapeutic options. The choice of treatment should take into consideration the patient's age and other associated conditions.

Other Uses with Supportive Evidence

Dravet syndrome is a rare genetic epileptic encephalopathy (dysfunction of the brain) marked with frequent and/or prolonged seizures.^{7,8} It has been estimated that 1 out of 20,000 to 40,000 infants born in the US are affected with Dravet syndrome. The seizures generally begin in the first year of life in an otherwise healthy infant. Affected individuals can develop many seizure types: myoclonic, tonic-clonic, absence, atypical absence, atonic, focal aware or impaired awareness (previously called partial seizures), and status epilepticus.⁸ As the seizures continue, most of the children develop some level of developmental disability and other conditions associated with the syndrome. Two or more ASMs are often needed to control the seizures; most of the seizures are refractory to medications. The goals of treatment are cessation of prolonged convulsions, reductions in overall seizure frequency, and minimization of treatment side effects.^{9,10} Some patients respond to the ketogenic diet and/or vagus nerve stimulation.

Guidelines/Recommendations

The American Academy of Neurology and the American Epilepsy Society published a guideline update for treatment-resistant epilepsy (2018) stating that clobazam is probably effective as add-on therapy for LGS and is possibly effective as add-on therapy for treatment-resistant adult focal epilepsy.¹³ Adjunctive therapy with clobazam has been effective in the treatment of uncontrolled or refractory epilepsy in adults and children.¹⁴ If first-line treatment is ineffective or not tolerated, clobazam has been used as adjunctive treatment of refractory focal seizures (partial seizure and localization-related seizure) in children, young adults, and adults; adjunctive treatment of generalized tonic-clonic seizures in children, young adults, and adults; and adjunctive treatment of children and young adults with benign epilepsy with centrotemporal spikes, Panayiotopoulos syndrome or late-onset childhood occipital epilepsy (Gastaut type).

Lennox-Gastaut Syndrome

Currently, the FDA-approved drugs for this condition are Epidiolex® (cannabidiol oral solution), felbamate, lamotrigine, rufinamide tablets and oral suspension, topiramate, clobazam, and Fintepla® (fenfluramine oral solution).^{11,14} Despite the lack of level I or level II evidence, valproic acid remains a mainstay in treatment.^{5,6,12} If valproic acid does not provide adequate seizure control, which is almost always the case, lamotrigine should be added as the first adjunctive therapy.⁴ If the combination regimen of valproic acid and lamotrigine does not provide adequate control, then rufinamide should be initiated and either valproic acid or lamotrigine should be discontinued. If seizure control is still not achieved, the next adjunctive therapies to consider are topiramate, clobazam, and felbamate. There is limited evidence for the use of levetiracetam, zonisamide, and Fycompa® (perampanel tablet, oral suspension). Where possible, no more than two ASMs should be used concomitantly; use of multiple ASMs raises the risk of adverse effects and/or drug-drug interactions.

Dravet Syndrome

Valproic acid and clobazam are considered to be the first-line treatment for Dravet syndrome.^{7,9,10} If seizure control is suboptimal, Diacomit® (stiripentol capsules), Epidiolex, Fintepla, and topiramate are treatment options. If control is still inadequate, other therapies to consider are clonazepam, levetiracetam, and zonisamide. Drugs that should be avoided in Dravet syndrome include sodium channel blockers (e.g., carbamazepine, oxcarbazepine, lamotrigine, and phenytoin), Sabril® (vigabatrin tablet, oral packet), and tiagabine.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of clobazam. Because of the specialized skills required for evaluation and diagnosis of patients treated with clobazam as well as the monitoring required for adverse events and long-term efficacy, initial approval requires clobazam to be prescribed by or in consultation with a physician who specializes in the condition being treated. All approvals are provided for the duration noted below.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of clobazam is recommended in those who meet one of the following criteria:

FDA-Approved Indication

7. **Lennox-Gastaut Syndrome.** Approve for 1 year if the patient meets ONE of the following (A or B):
 - A) **Initial Therapy.** Approve if the patient meets ALL of the following (i, ii, and iii):
 - i. Patient is ≥ 2 years of age; AND
 - ii. Patient has tried and/or is concomitantly receiving ONE of the following (a or b):
 - a) At least two other antiseizure medications; OR
Note: Examples of other antiseizure medications include valproic acid, levetiracetam, zonisamide, Fycompa (perampanel), vigabatrin, others.
 - b) One of lamotrigine, topiramate, rufinamide, felbamate, Fintepla (fenfluramine oral solution), or Epidiolex (cannabidiol oral solution); AND
 - iii. Clobazam is prescribed by or in consultation with a neurologist.
 - B) **Patient is Currently Receiving Clobazam.** Approve if the patient is responding to therapy, as determined by the prescriber.

Note: Examples of therapy response include reduced seizure severity, frequency, and/or duration from baseline (prior to initiation of clobazam).

Other Uses with Supportive Evidence

8. Dravet Syndrome. Approve for 1 year if the patient meets ONE of the following (A or B):

A) Initial Therapy. Approve if the patient meets BOTH of the following (i and ii):

- i.** Patient is ≥ 2 years of age; AND
- ii.** Clobazam is prescribed by or in consultation with a neurologist.

B) Patient is Currently Receiving Clobazam. Approve if the patient is responding to therapy, as determined by the prescriber.

Note: Examples of therapy response include reduced seizure severity, frequency, and/or duration from baseline (prior to initiation of clobazam).

3. Treatment-Refractory Seizures/Epilepsy. Approve for 1 year if the patient meets ONE of the following (A or B):

A) Initial Therapy. Approve if the patient meets ALL of the following (i, ii, and iii):

- i.** Patient is ≥ 2 years of age; AND
- ii.** Patient has tried and/or is concomitantly receiving at least two other antiseizure medications; AND

Note: Examples of other antiseizure medications are valproic acid, lamotrigine, topiramate, clonazepam, levetiracetam, zonisamide, rufinamide, felbamate.

- iii.** Clobazam is prescribed by or in consultation with a neurologist.

B) Patient is Currently Receiving Clobazam. Approve if the patient is responding to therapy, as determined by the prescriber.

Note: Examples of therapy response include reduced seizure severity, frequency, and/or duration from baseline (prior to initiation of clobazam).

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of clobazam is not recommended in the following situations:

26. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Antiseizure Medications – Diacomit Prior Authorization Policy

- Diacomit® (stiripentol capsules and powder for oral suspension – Biocodex)

REVIEW DATE: 02/07/2024

OVERVIEW

Diacomit, an antiseizure medication (ASM), is indicated for the treatment of seizures associated with **Dravet syndrome** in patients ≥ 6 months of age and weighing ≥ 7 kg taking clobazam.¹ There are no clinical data to support the use of Diacomit as monotherapy in Dravet syndrome.

Disease Overview

Dravet syndrome is a rare genetic epileptic encephalopathy (dysfunction of the brain) marked with frequent and/or prolonged seizures.^{2,3} The seizures generally begin in the first year of life in an otherwise healthy infant. Affected individuals can develop many seizure types: myoclonic, tonic-clonic, absence, atypical absence, atonic, focal aware or impaired awareness (previously called partial seizures), and status epilepticus.³ Two or more ASMs are often needed to control the seizures; most of the seizures are refractory to medications. The goals of treatment are cessation of prolonged convulsions, reduction in overall seizure frequency, and minimization of treatment side effects.^{4,5}

Clinical Efficacy in Other Refractory Seizures

In one study (n = 212), Diacomit was studied in children with different types of epilepsy syndromes (including Lennox-Gastaut Syndrome [LGS]; infantile spasms; infection-related or anoxo-ischemic epilepsy syndromes; tuberous sclerosis complex; Sturge-Weber syndrome; Doose syndrome; cortical malformation/dysplasia; and epilepsy with myoclonic absences) whose seizures were refractory to more than two ASMs (including vigabatrin).⁶ In the 88 patients who completed the 3-month placebo-controlled study, 56.8% of patients with partial epilepsy responded (with 14% becoming seizure-free) compared with 41.9% of patients with generalized epilepsy and 38.4% of patients with myoclonic epilepsy. Diacomit has also been administered to patients with refractory epileptic encephalopathies due to etiologies other than Dravet syndrome.⁷ A single-blind, exploratory trial evaluated Diacomit in combination with standard treatment in 16 patients with LGS and eight patients with symptomatic generalized epilepsy of the Lennox-Gastaut type.⁸ There were 15 evaluable patients with LGS. The overall results identified some benefit for LGS where 60% of patients were responders (based on 50% responder rate). Diacomit treatment produced a mean 62% seizure reduction and median 80% reduction from baseline. Additionally, a published study of Diacomit added to carbamazepine in childhood partial epilepsy (n = 67) demonstrated seizure response in 32 patients with conditions including herpetic encephalitis, LGS, and tuberous sclerosis complex.⁹

Guidelines/Recommendations

At this time, there are three drugs approved for the treatment of seizures associated with Dravet syndrome: Diacomit, Epidiolex® (cannabidiol oral solution), and Fintepla® (fenfluramine oral solution).^{1,10,11} An expert panel considers valproic acid and clobazam to be the first-line treatment for Dravet syndrome.⁵ If seizure control is suboptimal, Diacomit and topiramate are second-line treatment. Ketogenic diet is moderately effective and can also be considered second-line. The Dravet Foundation states that Diacomit, Epidiolex, and Fintepla are considered first-line agents for the treatment of Dravet syndrome.² If control is still inadequate, other therapies to consider are clonazepam, levetiracetam, and zonisamide.^{2,4,5} Sodium channel blockers (e.g., carbamazepine, oxcarbazepine, lamotrigine, and phenytoin) can worsen seizures in

Dravet syndrome. Additionally, vigabatrin and tiagabine may increase the frequency of myoclonic seizures and should be avoided.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Diacomit. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Diacomit as well as the monitoring required for adverse events and long-term efficacy, initial approval requires Diacomit to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Diacomit is recommended in those who meet one of the following criteria:

FDA-Approved Indication

- 9. Dravet Syndrome.** Approve for 1 year if the patient meets ONE of the following (A or B):
- C) Initial Therapy:** Approve if the patient meets the following (i, ii, and iii):
- i.** Patient is ≥ 6 months of age and weighs ≥ 7 kg; AND
 - ii.** Patient meets ONE of the following (a or b):
 - a)** Patient is taking concomitant clobazam; OR
 - b)** Patient is unable to take clobazam due to adverse events as determined by the prescriber; AND
 - iii.** The medication is prescribed by or in consultation with a neurologist; OR
- D) Patient is Currently Receiving Diacomit:** Approve if the patient is responding to therapy (e.g., reduced seizure severity, frequency, and/or duration) as determined by the prescriber.

Other Uses with Supportive Evidence

- 2. Treatment-Refractory Seizures/Epilepsy (specific rare conditions)** [i.e., Lennox-Gastaut Syndrome; infantile spasms; tuberous sclerosis complex; Sturge-Weber syndrome; Doose syndrome; infection-related or anoxo-ischemic epilepsy syndromes; cortical malformation/dysplasia; epileptic encephalopathies associated with sodium channel mutations; and epilepsy with myoclonic absences]. Approve for 1 year if the patient meets ONE of the following (A or B):
- C) Initial Therapy:** Approve if the patient meets the following (i, ii, and iii):
- i.** Patient is ≥ 6 months of age and weighs ≥ 7 kg; AND
 - ii.** Patient has tried at least two other antiseizure medications; AND
Note: Examples of other antiseizure medications include valproic acid, lamotrigine, topiramate, clonazepam, Banzel® (rufinamide tablet, oral suspension), felbamate, clobazam, Fycompa® (perampanel tablet, oral suspension), vigabatrin, levetiracetam, zonisamide.
 - iii.** The medication is prescribed by or in consultation with a neurologist; OR
- D) Patient is Currently Receiving Diacomit:** Approve if the patient is responding to therapy (e.g., reduced seizure severity, frequency, and/or duration) as determined by the prescriber.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Diacomit is not recommended in the following situations:

27. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

POLICY: Antiseizure Medications – Epidiolex Prior Authorization Policy

- Epidiolex® (cannabidiol oral solution – Greenwich Biosciences)

REVIEW DATE: 02/07/2024

OVERVIEW

Epidiolex, a cannabinoid, is indicated in patients ≥ 1 year of age for the **treatment of seizures associated with:**¹

- **Dravet syndrome.**
- **Lennox-Gastaut syndrome.**
- **Tuberous sclerosis complex.**

Disease Overview

Dravet syndrome is a rare genetic epileptic encephalopathy marked with frequent and/or prolonged seizures.^{2,3} The seizures generally begin in the first year of life in an otherwise healthy infant. Affected individuals can develop many seizure types: myoclonic, tonic-clonic, absence, atypical absence, atonic, focal aware or impaired awareness (previously called partial seizures), and status epilepticus.³ Two or more antiseizure medications (ASMs) are often needed to control the seizures; most of the seizures are refractory to medications. The goals of treatment are cessation of prolonged convulsions, reduction in overall seizure frequency, and minimization of treatment side effects.^{4,5}

Lennox-Gastaut syndrome, a severe epileptic and developmental encephalopathy, is associated with a high rate of morbidity and mortality.^{6,7} Lennox-Gastaut syndrome most often begins between 3 and 5 years of age.^{6,9} Affected children experience several different types of seizures, most commonly atonic seizures (sudden loss of muscle tone and limpness) and tonic seizures.^{6,9} The three main forms of treatment of Lennox-Gastaut syndrome are ASMs, dietary therapy (typically the ketogenic diet), and device/surgery (e.g., vagus nerve stimulation, corpus callostomy).⁹ None of the therapies are effective in all cases of Lennox-Gastaut syndrome and the disorder has proven particularly resistant to most therapeutic options.

Tuberous sclerosis complex is a rare, genetic disease that causes non-cancerous (benign) tumors to grow in the brain and on other vital organs such as the kidneys, heart, eyes, lungs, and skin.¹⁰ It can result in a combination of symptoms including seizures, impaired intellectual development, autism, behavioral problems, skin abnormalities, and kidney disease. Seizures affect most individuals with tuberous sclerosis complex at some point during their life and can be difficult to control.

Clinical Efficacy in Other Refractory Seizures

In 2014, an expanded access program was initiated to provide Epidiolex to patients with treatment-resistant epilepsy.¹⁴ Of the 840 patients included in a published review, 192 patients were diagnosed with Dravet syndrome or Lennox-Gastaut syndrome, and 648 patients were diagnosed with other conditions, including CDKL5 deficiency disorder, Dup15q, Aicardi, and Doose syndromes; febrile infection-related epilepsy syndromes; tuberous sclerosis complex; Sturge-Weber syndrome; lissencephaly; cortical malformation/dysplasia; and myoclonic absence. The patients enrolled in the study had severe, intractable, childhood-onset treatment-resistant epilepsy and were on stable doses of ASMs for 4 weeks before starting Epidiolex as add-on therapy. The initial dose of Epidiolex was 2 to 10 mg/kg/day (taken as two divided doses) and gradually titrated until intolerance or to a maximum dose of 25 mg/kg/day or 50 mg/kg/day, depending upon treatment site. Of those enrolled in the expanded access program, 892 patients were

02/07/2024

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

evaluated and included in the safety analysis set and 840 patients were included in the efficacy analysis set. Through 192 weeks, the median percentage reduction in seizure frequency across visit windows ranged from 50% to 67% for convulsive seizures and 46% to 66% for total seizures. In a cohort of 132 patients (72 children, 60 adults) with treatment-resistant epilepsy, bi-weekly seizure frequency decreased from a mean of 144.4 at entry to 52.2 at 12 weeks ($P = 0.01$) and remained stable thereafter.¹⁵ Of note, patients with a diagnosis of Lennox-Gastaut syndrome or Dravet syndrome were initially excluded because of preferential enrollment into the randomized clinical trials; once these trials were closed for enrollment, patients with these syndromes were also enrolled. In a separate cohort of patients with CDKL5 deficiency disorder and Aicardi, Doose, and Dup15q syndromes ($n = 46$), the percent change in median convulsive seizure frequency decreased from baseline to Week 12 by 51.4% and by 59.1% at Week 48.¹⁶ There was a significant difference between the percent changes in monthly convulsive seizure frequency during baseline and Week 12 ($P = 0.00001$), with no difference in seizure percent change between Weeks 12 and 48. Of the 55 patients in the safety group, 27% of patients withdrew by Week 144 due to adverse effects ($n = 4$), lack of efficacy ($n = 9$), withdrawn consent ($n = 1$), and lost to follow-up ($n = 1$).

Guidelines/Recommendations

Dravet Syndrome

At this time, there are three drugs approved for the treatment of seizures associated with Dravet syndrome: Epidiolex, Diacomit[®] (stiripentol capsules, powder for oral suspension), and Fintepla[®] (fenfluramine oral solution).^{1,11,17} An expert panel considers valproic acid and clobazam to be the first-line treatment for Dravet syndrome.⁴ If seizure control is suboptimal, Diacomit and topiramate are second-line treatment. Ketogenic diet is moderately effective and can also be considered second-line. The Dravet Foundation states that Diacomit, Epidiolex, and Fintepla are considered first-line agents for the treatment of Dravet syndrome.² If control is still inadequate, other therapies to consider are clonazepam, levetiracetam, and zonisamide.^{2,4} Sodium channel blockers (e.g., carbamazepine, oxcarbazepine, lamotrigine, and phenytoin) can worsen seizures in Dravet syndrome. Additionally, vigabatrin and tiagabine may increase the frequency of myoclonic seizures and should be avoided.

Lennox-Gastaut Syndrome

Currently, the FDA-approved drugs for this condition are Epidiolex, Fintepla, felbamate, Banzel[®] (rufinamide tablet, oral suspension), lamotrigine, topiramate, and clobazam.¹² Despite the lack of level I or level II evidence, valproic acid remains a mainstay in treatment.^{8,9,13} If valproic acid does not provide adequate seizure control, which is almost always the case, lamotrigine should be added as the first adjunctive therapy.⁷ If the combination regimen of valproic acid and lamotrigine does not provide adequate control, then Banzel should be initiated and either valproic acid or lamotrigine should be discontinued. If seizure control is still not achieved, the next adjunctive therapies to consider are topiramate, clobazam, and felbamate. There is limited evidence for the use of levetiracetam, zonisamide, and Fycompa[®] (perampanel tablet, oral suspension). Where possible, no more than two ASMs should be used concomitantly; use of multiple ASMs raise the risk of side effects and/or drug-drug interactions.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Epidiolex. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Epidiolex as well as the monitoring required for adverse events and long-term efficacy, initial approval requires Epidiolex to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Epidiolex is recommended in those who meet the following criteria:

FDA-Approved Indications

10. Dravet Syndrome. Approve if the patient meets ONE of the following (A or B):

E) Initial Therapy. Approve for 1 year if the patient meets the following (i, ii, and iii):

iv. Patient is ≥ 1 year of age; AND

v. Patient meets ONE of the following (a or b):

i. Patient has tried or is concomitantly receiving at least two other antiseizure medications;
OR

Note: Examples of other antiseizure medications include valproic acid, topiramate, clonazepam, levetiracetam, zonisamide.

ii. Patient has tried or is concomitantly receiving one of Fintepla, Diacomit or clobazam; AND

vi. The medication is prescribed by or in consultation with a neurologist.

F) Patient is Currently Receiving Epidiolex. Approve for 1 year if the patient is responding to therapy (e.g., reduced seizure severity, frequency, and/or duration) as determined by the prescriber.

11. Lennox-Gastaut Syndrome. Approve if the patient meets ONE of the following (A or B):

C) Initial Therapy. Approve for 1 year if the patient meets the following (i, ii, and iii):

1. Patient is ≥ 1 year of age; AND

2. Patient has tried or is concomitantly receiving at least two other antiseizure medications; AND

Note: Examples of other antiseizure medications include lamotrigine, topiramate, Banzel, felbamate, clobazam, valproic acid, levetiracetam, zonisamide, Fycompa, vigabatrin.

3. The medication is prescribed by or in consultation with a neurologist.

D) Patient is Currently Receiving Epidiolex. Approve for 1 year if the patient is responding to therapy (e.g., reduced seizure severity, frequency, and/or duration) as determined by the prescriber.

12. Tuberous Sclerosis Complex. Approve if the patient meets ONE of the following (A or B):

A) Initial Therapy. Approve for 1 year if the patient meets the following (i, ii, and iii):

1. Patient is ≥ 1 year of age; AND

2. Patient has tried or is concomitantly receiving at least two other antiseizure medications; AND

Note: Examples of other antiseizure medications include valproic acid, lamotrigine, topiramate, clonazepam, levetiracetam, zonisamide, Banzel, felbamate, clobazam, Fycompa, vigabatrin, everolimus.

3. The medication is prescribed by or in consultation with a neurologist.

B) Patient is Currently Receiving Epidiolex. Approve for 1 year if the patient is responding to therapy (e.g., reduced seizure severity, frequency, and/or duration) as determined by the prescriber.

Other Uses with Supportive Evidence

4. Treatment-Refractory Seizures/Epilepsy [specific rare conditions] (i.e., CDKL5 deficiency disorder; Dup15q, Aicardi, or Doose syndromes; febrile infection-related epilepsy syndromes; Sturge-Weber syndrome; lissencephaly; cortical malformation/dysplasia; and epilepsy with myoclonic absences). Approve if the patient meets ONE of the following (A or B):

E) Initial Therapy. Approve for 1 year if the patient meets the following (i, ii, and iii):

iv. Patient is ≥ 1 year of age; AND

v. Patient has tried or is concomitantly receiving at least two other antiseizure medications; AND

- Note: Examples of other antiseizure medications include valproic acid, lamotrigine, topiramate, clonazepam, levetiracetam, zonisamide, Banzel, felbamate, clobazam, Fycompa, vigabatrin.
- vi. The medication is prescribed by or in consultation with a neurologist.
- F) Patient is Currently Receiving Epidiolex. Approve for 1 year if the patient is responding to therapy (e.g., reduced seizure severity, frequency, and/or duration) as determined by the prescriber.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Epidiolex is not recommended in the following situations:

1. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Antiseizure Medications – Fintepla Prior Authorization Policy

- Fintepla® (fenfluramine oral solution – Zogenix)

REVIEW DATE: 04/19/2024

OVERVIEW

Fintepla, a serotonin 5-hydroxytryptamine subtype 2 (5-HT₂) agonist, is indicated in patients ≥ 2 years of age for the treatment of **seizures associated with:**

- **Dravet syndrome.**
- **Lennox-Gastaut syndrome.**

Disease Overview

Dravet syndrome is a rare genetic epileptic encephalopathy (dysfunction of the brain) marked with frequent and/or prolonged seizures.^{2,3} It is estimated that 1 out of 15,700 infants born in the US are affected with Dravet syndrome. The seizures generally begin in the first year of life in an otherwise healthy infant. Affected individuals can develop many seizure types: myoclonic, tonic-clonic, absence, atypical absence, atonic, focal aware or impaired awareness (previously called partial seizures), and status epilepticus.³ As the seizures continue, most of the children develop some level of developmental disability and other conditions associated with the syndrome. Two or more antiseizure medications (ASMs) are often needed to control the seizures; most of the seizures are refractory to medications. The goals of treatment are cessation of prolonged convulsions, reductions in overall seizure frequency, and minimization of treatment side effects.^{4,5} Some patients respond to the ketogenic diet and/or vagus nerve stimulation.

Lennox-Gastaut syndrome, a severe epileptic and developmental encephalopathy, is associated with a high rate of morbidity and mortality.^{6,7} Lennox-Gastaut syndrome most often begins between 3 and 5 years of age.^{6,9} Affected children experience several different types of seizures, most commonly atonic seizures (sudden loss of muscle tone and limpness) and tonic seizures.^{6,9} The three main forms of treatment of Lennox-Gastaut syndrome are ASMs, dietary therapy (typically the ketogenic diet), and device/surgery (e.g., vagus nerve stimulation, corpus callostomy).⁹ None of the therapies are effective in all cases of Lennox-Gastaut syndrome and the disorder has proven particularly resistant to most therapeutic options.

Guidelines

Fintepla is not mentioned in the current treatment recommendations.

Dravet Syndrome

At this time, there are three drugs approved for the treatment of seizures associated with Dravet syndrome: Diacomit® (stiripentol capsules, powder for oral suspension), Epidiolex® (cannabidiol oral solution), and Fintepla.^{1,10} An expert panel considers valproic acid to be the first-line treatment for Dravet syndrome.⁴ Clobazam, Diacomit, and Fintepla can be considered as either first- or second-line ASMs. Cannabidiol was supported either as first- or second-line treatment. There was modest consensus among caregivers, but no consensus among physicians to support topiramate as first-, second-, or third-line therapy. The Dravet Foundation states that Diacomit, Epidiolex, and Fintepla are considered first-line agents for the treatment of Dravet syndrome.² If control is still inadequate, other therapies to consider are clonazepam, levetiracetam, and zonisamide.^{2,4} Sodium channel blockers (e.g., carbamazepine, oxcarbazepine, lamotrigine, and phenytoin) can worsen seizures in Dravet syndrome. Additionally, vigabatrin and tiagabine may increase the frequency of myoclonic seizures and should be avoided.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Lennox-Gastaut Syndrome

Currently, the FDA-approved drugs for this condition are Fintepla, clobazam, clonazepam, rufinamide, Epidiolex, felbamate, lamotrigine, and topiramate. Despite the lack of level I or level II evidence, valproic acid remains a mainstay in treatment.^{8,9,12} If valproic acid does not provide adequate seizure control, which is almost always the case, lamotrigine should be added as the first adjunctive therapy.⁷ If the combination regimen of valproic acid and lamotrigine does not provide adequate control, then rufinamide should be initiated and either valproic acid or lamotrigine should be discontinued. If seizure control is still not achieved, the next adjunctive therapies to consider are topiramate, clobazam, and felbamate. There is limited evidence for the use of levetiracetam, zonisamide, and Fycompa® (perampanel tablet, oral suspension). Where possible, no more than two ASMs should be used concomitantly; use of multiple ASMs raise the risk of side effects and/or drug-drug interactions.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Fintepla. Because of the specialized skills required for evaluation and diagnosis of patients treated with Fintepla as well as the monitoring required for adverse events and long-term efficacy, initial approval requires Fintepla to be prescribed by or in consultation with a physician who specializes in the condition being treated. All approvals are provided for the duration noted below.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Fintepla is recommended in those who meet the following criteria:

FDA-Approved Indications

13. Dravet Syndrome. Approve if the patient meets ONE the following (A or B):

- A) Initial Therapy. Approve for 1 year if the patient meets ALL of the following (i, ii, and iii):
 - i. Patient is ≥ 2 years of age; AND
 - ii. Patient meets ONE of the following (a or b):
 - a) Patient has tried or is concomitantly receiving at least two other antiseizure medications; OR
Note: Examples of other antiseizure medications include valproic acid, topiramate, clonazepam, levetiracetam, zonisamide.
 - b) Patient has tried or is concomitantly receiving one of clobazam, Epidiolex or Diacomit; AND
 - iii. Fintepla is prescribed by or consultation with a neurologist; OR
- B) Patient is Currently Receiving Fintepla. Approve for 1 year if the patient is responding to therapy (e.g., reduced seizure severity, frequency, and/or duration) as determined by the prescriber.

14. Lennox-Gastaut Syndrome. Approve if the patient meets ONE of the following (A or B):

- E) Initial Therapy. Approve for 1 year if the patient meets ALL of the following (i, ii, and iii):
 - 1. Patient is ≥ 2 years of age; AND
 - 2. Patient has tried or is concomitantly receiving at least two other antiseizure medications; AND
Note: Examples of other antiseizure medications include clobazam, Epidiolex, felbamate, lamotrigine, rufinamide, topiramate, valproic acid, levetiracetam, zonisamide, Fycompa, vigabatrin.

3. The medication is prescribed by or in consultation with a neurologist.
- F) Patient is Currently Receiving Fintepla. Approve for 1 year if the patient is responding to therapy (e.g., reduced seizure severity, frequency, and/or duration) as determined by the prescriber.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Fintepla is not recommended in the following situations:

16. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Antiseizure Medications – Nayzilam Prior Authorization Policy

- Nayzilam® (midazolam nasal spray – UCB)

REVIEW DATE: 09/18/2024

OVERVIEW

Nayzilam, a benzodiazepine, is indicated for the acute treatment of **intermittent, stereotypic episodes of frequent seizure activity** (i.e., seizure clusters, acute repetitive seizures) that are distinct from a patient's usual seizure pattern, in patients with epilepsy ≥ 12 years of age.¹

Disease Overview

Patients with epilepsy can experience acute repetitive seizures or seizure clusters.² No consensus definition of a seizure cluster has been agreed upon.³ A broad definition of seizure clusters has been proposed to be “acute episodes of deterioration in seizure control”. More specifically, they could be defined as a series of grouped seizures that have short interictal periods. However, the number of seizures and the interictal period are the subject of controversy. Seizure clusters can result in increased emergency room visits or hospitalization, and they can disrupt the daily life, studies, and work of patients and caregivers. They are particularly concerning because of their association with status epilepticus, a potentially life-threatening condition. Benzodiazepine rescue medication is the primary acute therapy for management of seizure clusters, helping to abort clusters and reduce emergency department visits.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Nayzilam. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Nayzilam as well as the monitoring required for adverse events and efficacy, approval requires Nayzilam to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Nayzilam is recommended in those who meet the following criteria:

FDA-Approved Indication

15. Intermittent Episodes of Frequent Seizure Activity (i.e., seizure clusters, acute repetitive seizures). Approve for 1 year if the patient meets BOTH of the following (A and B):

- A)** Patient is currently receiving maintenance antiseizure medication(s); AND
- B)** The medication is prescribed by or in consultation with a neurologist.

PRIOR AUTHORIZATION POLICY

POLICY: Antiseizure Medications – Rufinamide Prior Authorization Policy

- Banzel® (rufinamide tablets and oral suspension – Eisai, generic)

REVIEW DATE: 09/18/2024

OVERVIEW

Rufinamide is indicated for adjunctive treatment of **seizures associated with Lennox-Gastaut syndrome (LGS)** in patients ≥ 1 year of age.¹

Although rufinamide is only FDA-approved for use in LGS, clinical trial data indicate the drug may also be beneficial as adjunctive treatment of refractory focal epilepsy.² A review of six clinical trials found that rufinamide, when used as an add-on treatment, was effective in reducing seizure frequency in patients with drug-resistant focal epilepsy.

Disease Overview

LGS is a severe epileptic and developmental encephalopathy associated with a high rate of morbidity and mortality.^{3,4} LGS most often begins between 3 years and 5 years of age and comprises approximately 3% to 4% of childhood epilepsies.³⁻⁶ Affected children experience several different types of seizures, most commonly atonic seizures (sudden loss of muscle tone and limpness, also called drop seizures) and tonic seizures (increased muscle tone and muscle stiffness).^{3,6} The three main forms of treatment of LGS are antiseizure medications (ASMs), dietary therapy (typically the ketogenic diet), and device/surgery (e.g., vagus nerve stimulation, corpus callosotomy).⁶ None of the therapies are effective in all cases of LGS and the disorder has proven particularly resistant to most therapeutic options. The choice of treatment should take into consideration the patient's age and other associated conditions.

Guidelines/Recommendations

Lennox-Gastaut syndrome: Currently, the FDA-approved drugs for this condition are Epidiolex® (cannabidiol oral solution), felbamate, lamotrigine, rufinamide, topiramate, and clobazam.⁷ Despite the lack of level I or level II evidence, valproic acid remains a mainstay in treatment.^{5,6,8} If valproic acid does not provide adequate seizure control, which is almost always the case, lamotrigine should be added as the first adjunctive therapy.⁴ If the combination regimen of valproic acid and lamotrigine does not provide adequate control, then rufinamide should be initiated and either valproic acid or lamotrigine should be discontinued. If seizure control is still not achieved, the next adjunctive therapies to consider are topiramate, clobazam, and felbamate. There is limited evidence for the use of levetiracetam, zonisamide, and Fycompa® (perampanel tablets and oral suspension). Where possible, no more than two ASMs should be used concomitantly; use of multiple ASMs raise the risk of side effects and/or drug-drug interactions.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of rufinamide. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with rufinamide as well as the monitoring required for adverse events and long-term efficacy, initial approval requires rufinamide to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

09/18/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of rufinamide is recommended in those who meet one of the following criteria:

FDA-Approved Indication

13. Lennox-Gastaut Syndrome. Approve for 1 year if the patient meets ONE of the following (A or B):

G) Initial Therapy. Approve if the patient meets ALL of the following (i, ii, and iii):

- i. Patient is ≥ 1 year of age; AND
- ii. Patient has tried and/or is concomitantly receiving at least two other antiseizure medications; AND

Note: Examples of antiseizure medications include valproic acid, gabapentin, phenytoin, carbamazepine, oxcarbazepine, lacosamide, levetiracetam, zonisamide, Fycompa (perampanel tablet or oral suspension), vigabatrin, lamotrigine, topiramate, clobazam, Diacomit (stiripentol capsules or oral suspension), Epidiolex (cannabidiol oral solution), and felbamate.

- iii. The medication is prescribed by or in consultation with a neurologist.

H) Patient is Currently Receiving rufinamide. Approve if the patient is responding to therapy (e.g., reduced seizure severity, frequency, and/or duration) as determined by the prescriber.

Other Uses with Supportive Evidence

5. Treatment-Refractory Seizures/Epilepsy. Approve for 1 year if the patient meets ONE of the following (A or B):

G) Initial Therapy. Approve if the patient meets ALL of the following (i, ii, and iii):

- vii. Patient is ≥ 1 year of age; AND
- viii. Patient has tried and/or is concomitantly receiving at least two other antiseizure medications; AND

Note: Examples of antiseizure medications include valproic acid, gabapentin, phenytoin, carbamazepine, oxcarbazepine, lacosamide, levetiracetam, zonisamide, Fycompa (perampanel tablet or oral suspension), vigabatrin, lamotrigine, topiramate, clobazam, Diacomit (stiripentol capsules or oral suspension), Epidiolex (cannabidiol oral solution), and felbamate.

- ix. The medication is prescribed by or in consultation with a neurologist.

H) Patient is Currently Receiving rufinamide. Approve if the patient is responding to therapy (e.g., reduced seizure severity, frequency, and/or duration) as determined by the prescriber.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of rufinamide is not recommended in the following situations:

28. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Antiseizure Medications – Valtoco Prior Authorization Policy

- Valtoco® (diazepam nasal spray – Neurelis)

REVIEW DATE: 02/07/2024

OVERVIEW

Valtoco, a benzodiazepine, is indicated for the acute treatment of **intermittent, stereotypic episodes of frequent seizure activity** (i.e., seizure clusters, acute repetitive seizures) that are distinct from a patient's usual seizure pattern in patients with epilepsy ≥ 6 years of age.¹

Valtoco is for acute treatment only. Do not use more than two doses of Valtoco to treat a single episode.¹ It is recommended that Valtoco be used to treat no more than one episode every 5 days and no more than five episodes per month.

Disease Overview

Patients with epilepsy can experience acute repetitive seizures or seizure clusters.² Patients with severe and/or poorly controlled epilepsy are more likely to experience seizure clusters. Seizure clusters can result in increased emergency room visits or hospitalization, and they can disrupt the daily life, studies, and work of patients and caregivers. They are particularly concerning because of their association with status epilepticus, a potentially life-threatening condition. Benzodiazepine rescue medication is the primary acute therapy for management of seizure clusters, helping to abort clusters and reduce emergency department visits.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Valtoco. All approvals are provided for the duration noted below.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Valtoco is recommended in those who meet the following criteria:

FDA-Approved Indication

16. Intermittent Episodes of Frequent Seizure Activity (i.e., seizure clusters, acute repetitive seizures). Approve for 1 year if the patient meets the following (A and B):

- A)** Patient is currently receiving maintenance antiseizure medication(s); AND
- B)** The medication is prescribed by or in consultation with a neurologist.

02/07/2024

PRIOR AUTHORIZATION POLICY

- POLICY:** Antiseizure Medications – Vigabatrin Prior Authorization Policy
- Sabril® (vigabatrin tablets and powder for solution – Lundbeck, generic)
 - Vigpoder™ (vigabatrin powder for oral solution – Pyros [branded generic to Sabril powder for solution])
 - Vigadrone® (vigabatrin tablets and oral solution – Upsher-Smith [branded generic to Sabril])
 - Vigafyde™ (vigabatrin oral solution – Pyros)

REVIEW DATE: 04/19/2024; selected revision 09/18/2024

OVERVIEW

Vigabatrin (Sabril, generic) is indicated for the following uses:¹⁻³

- **Infantile spasms**, as monotherapy, in patients 1 month to 2 years of age for whom the potential benefits outweigh the potential risk of vision loss.
- **Refractory complex partial seizures**, as adjunctive therapy, in patients ≥ 2 years of age who have inadequately responded to several alternative treatments and for whom the potential benefits outweigh the risk of vision loss. Vigabatrin is not indicated as a first-line agent for complex partial seizures.

Vigafyde is indicated as monotherapy for the treatment of infantile spasms in pediatric patients 1 month to 2 years of age for whom the potential benefits outweigh the potential risk of vision loss.⁴

According to the vigabatrin prescribing information, use the lowest dosage and shortest exposure to vigabatrin consistent with clinical objectives.¹⁻⁴ In patients with infantile spasms, vigabatrin should be withdrawn if a substantial clinical benefit is not observed within 2 to 4 weeks. In patients with refractory complex partial seizures, vigabatrin should be withdrawn if a substantial clinical benefit is not observed within 3 months of initiating treatment.¹⁻³

Safety

Vigabatrin has a Boxed Warning with regard to permanent vision loss.¹⁻⁴ In some cases, vigabatrin can also damage the central retina and may decrease visual acuity. The onset of vision loss from vigabatrin is unpredictable, and can occur within weeks of starting treatment or sooner, or at any time after starting treatment, even after months or years. The risk of vision loss increases with increasing dose and cumulative exposure, but there is no dose or exposure known to be free of risk of vision loss. Vision assessment is recommended at baseline (no later than 4 weeks after starting vigabatrin), at least every 3 months during therapy, and about 3 to 6 months after the discontinuation of therapy. Once detected, vision loss due to vigabatrin is not reversible. Because of the risk of vision loss, vigabatrin should be withdrawn from patients with refractory complex partial seizures who fail to show substantial clinical benefit within 3 months of initiation and within 2 to 4 weeks of initiation for patients with infantile spasms, or sooner if treatment failure becomes obvious. Because of the risk of permanent vision loss, vigabatrin is available only through a restricted access program under a Risk Evaluation and Mitigation Strategy (REMS) called the Vigabatrin REMS Program.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Guidelines/Recommendations

In 2012, the American Academy of Neurology (AAN) and the Child Neurology Society updated the evidence-based guideline for the medical treatment of infantile spasms (retired April 15, 2024).⁵ The guidelines note that low-dose adrenocorticotrophic hormone (ACTH) is a first-line agent for the short-term treatment of infantile spasms. ACTH or vigabatrin may be useful for short-term treatment of infantile spasms, with ACTH considered preferentially over vigabatrin. Hormonal therapy (ACTH or prednisolone) may be considered for use in preference to vigabatrin in infants with cryptogenic infantile spasms, to possibly improve developmental outcome. A shorter lag time to treatment of infantile spasms with either hormonal therapy or vigabatrin possibly improves long-term developmental outcomes. The Infantile Spasms Working Group (ISWG) published a US consensus report on infantile spasms in 2010.⁶ Data regarding ACTH use and vigabatrin use in infantile spasms were detailed. ACTH is an effective first-line therapy for infantile spasms. Vigabatrin is considered a drug of first choice for infantile spasms with concomitant tuberous sclerosis complex, and it is the drug of second or third choice for children with other symptomatic or cryptogenic infantile spasms.

The AAN and the American Epilepsy Society published a guideline update for treatment-resistant epilepsy (2018) that notes clobazam is probably effective as add-on therapy for LGS and is possibly effective as add-on therapy for treatment-resistant adult focal epilepsy.⁷ Vigabatrin is effective as add-on therapy in treatment-resistant adult focal epilepsy based on two Class I studies, but it should not be used as a first-line treatment. The benefits of vigabatrin should be weighed against the risks, particularly the risk of irreversible retinopathy.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of vigabatrin. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with vigabatrin as well as the monitoring required for adverse events and long-term efficacy, initial approval requires vigabatrin to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of vigabatrin is recommended in those who meet one of the following criteria:

FDA-Approved Indications

14. Infantile Spasms. Approve for 6 months if the patient meets ALL of the following (A, B, and C):

- B)** Patient is ≤ 2 years of age; AND
- C)** Vigabatrin is being used as monotherapy; AND
- D)** The medication is prescribed by or in consultation with a neurologist.

15. Treatment-Refractory Complex Partial Seizures. Approve for the duration noted below if the patient meets ONE of the following (A or B):

- I) Initial Therapy.** Approve for 3 months if the patient meets ALL of the following (i, ii, and iii):
 - i. Patient is ≥ 2 years of age; AND
 - ii. Patient has tried and/or is concomitantly receiving at least three other antiseizure medications; AND

Note: Examples of antiseizure medications include valproic acid, gabapentin, phenytoin, carbamazepine, oxcarbazepine, lacosamide, levetiracetam, zonisamide, Fycompa (perampanel tablet or oral suspension), lamotrigine, topiramate, rufinamide, tiagabine, felbamate, Diacomit (stiripentol capsules or oral suspension), and clobazam.

iii. The medication is prescribed by or in consultation with a neurologist.

J) Patient is Currently Receiving Vigabatrin. Approve for 1 year if the patient is responding to therapy (e.g., reduced seizure severity, frequency, and/or duration) as determined by the prescriber.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of vigabatrin is not recommended in the following situations:

2. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Antiseizure Medications – Ztalmy Prior Authorization Policy

- Ztalmy® (ganaxolone oral suspension – Marinus)

REVIEW DATE: 07/31/2024

OVERVIEW

Ztalmy, a neuroactive steroid gamma-aminobutyric acid (GABA) A receptor positive modulator, is indicated for the treatment of **seizures associated with cyclin-dependent kinase-like 5 (CDKL5) deficiency disorder (CDD)** in patients ≥ 2 years of age.¹

Disease Overview

CDD is a rare, X-linked developmental epileptic encephalopathy caused by mutations in the CDKL5 gene.^{2,3} This disorder can manifest in a broad range of clinical symptoms, including early-onset (< 3 months of age in 90% of patients [median of 5 weeks]), hypotonia, intractable epilepsy, and neurodevelopmental delay impacting cognitive, motor, speech, and visual function. Both cognitive impairment and refractory epilepsy in individuals with CDD are particularly severe; less than 50% of patients have reported a period of seizure freedom > 2 months, with only 12% of patients experiencing seizure freedom for > 12 months. The CDKL5 gene provides instructions for making proteins that are essential for normal brain and neuron development. The CDKL5 protein acts as a kinase, an enzyme that changes the activity of other proteins by adding a phosphate group at specific positions; however, it has not yet been determined which proteins are targeted by the CDKL5 protein. Many cases of CDD have been identified in boys, but because of the location of the gene on the X chromosome, CDD primarily affects girls. Ztalmy is the first antiseizure medication that is FDA-approved for use in CDD and has been prospectively studied.

Clinical Efficacy

The efficacy of Ztalmy in patients with molecularly confirmed CDD was evaluated in one pivotal trial called the Marigold Study ($n = 101$).⁴ Eligible patients were 2 to 21 years of age and had a molecularly confirmed CDKL5 variant that was considered pathogenic or likely to be pathogenic. Patients could remain on a regimen of up to four concomitant antiseizure medications during the trial, including (but not limited to) valproate, levetiracetam, clobazam, and vigabatrin. During the 17-week double-blind phase, the median 28-day major motor seizure frequency was 45.0 in the Ztalmy arm vs. 55.5 in the placebo arm. Compared with the 6-week baseline period, the median percentage change in 28-day major motor seizure frequency was statistically significantly improved (reduced) in the Ztalmy arm vs. the placebo arm (-30.7% vs. -6.9% , respectively; $P = 0.0036$).

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Ztalmy. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Ztalmy as well as the monitoring required for adverse events and long-term efficacy, approval requires Ztalmy to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

07/31/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Coverage of Ztalmy is recommended in those who meet the following criteria:

FDA-Approved Indication

17. Seizures Associated with Cyclin-Dependent Kinase-Like 5 (CDKL5) Deficiency Disorder.

Approve for 1 year if the patient meets ALL of the following (A, B, C, and D):

- A)** Patient is ≥ 2 years of age; AND
- B)** Patient has a molecularly confirmed pathogenic or likely pathogenic mutation in the CDKL5 gene; AND
- C)** Patient has tried and/or is concomitantly receiving at least two other antiseizure medications; AND
Note: This can include any two antiseizure medications, including but not limited to, clobazam, Epidiolex (cannabidiol oral solution), lacosamide, lamotrigine, levetiracetam, phenobarbital, rufinamide, topiramate, valproate, vigabatrin, zonisamide.
- D)** The medication is prescribed by or in consultation with a neurologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Ztalmy is not recommended in the following situations:

- 19.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Antivirals – Ribavirin (Inhaled Products) Prior Authorization Policy

- Virazole® (ribavirin inhalation solution – Bausch, generic)

REVIEW DATE: 06/12/2024

OVERVIEW

Ribavirin is a synthetic nucleoside with antiviral activity.¹ Ribavirin inhalation solution (referred to as aerosolized ribavirin in this policy) is indicated for the treatment of hospitalized infants and young children with severe lower respiratory tract infections due to **respiratory syncytial virus (RSV)**. Treatment early in the course of severe lower respiratory tract infection may be necessary to achieve efficacy.

Disease Overview

RSV causes seasonal annual epidemics worldwide with year-round disease seen in some tropical locations. By 2 years of age, most children have experienced a primary infection; re-infection can occur throughout life.³ Subsequent infections are usually less severe than a primary infection, particularly among otherwise healthy older children and adults. Recurrent RSV infection manifests as mild upper respiratory tract illness and seldom involves the lower respiratory tract.²

Aerosolized ribavirin has also been used off-label in adults for RSV and for other respiratory viral infections, most commonly in immunocompromised patients.^{3,4}

Guidelines

The American Academy of Pediatrics (2024) states that no available treatment shortens the course of bronchiolitis or hastens the resolution of RSV symptoms.² Management of young children hospitalized with bronchiolitis is supportive. Because of limited evidence for a clinically relevant benefit, potential toxic effects, and high cost, routine use of aerosolized ribavirin is not recommended.

Guidelines from the American Society of Transplantation Infectious Diseases Community of Practice (2019) recommend aerosolized ribavirin in lung transplant recipients with upper or lower respiratory tract infection.³ Treatment with aerosolized or oral ribavirin for non-solid organ recipients with lower respiratory tract disease can be considered. Aerosolized ribavirin is also a therapeutic option in lung transplant recipients with parainfluenza virus and human metapneumovirus.

The National Comprehensive Cancer Network guidelines for the prevention and treatment of cancer-related infections (version 1.2024 – April 30, 2024) recommend consideration of aerosolized ribavirin for the treatment of lower respiratory tract RSV disease (category 3).⁴ Comments related to the recommendation are to limit use to patients undergoing stem cell transplant or with leukemia and, that despite limited information in immunocompromised adults with RSV, use should be considered given the potential morbidity and mortality associated with RSV infection.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of aerosolized ribavirin. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with aerosolized ribavirin as well as the monitoring required for adverse events and long-

06/12/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

term efficacy, approval requires aerosolized ribavirin to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of aerosolized ribavirin is recommended in those who meet one of the following criteria:

FDA-Approved Indication

- 18. Respiratory Syncytial Virus (RSV), Treatment.** Approve for 1 month if the patient meets ALL of the following (A, B, and C):
- A) Patient is < 2 years of age; AND
 - B) Patient is hospitalized; AND
 - C) The medication is prescribed by or in consultation with a critical care or pulmonary specialist.

Other Uses with Supportive Evidence

- 2. Respiratory Virus Treatment, Excluding COVID-19.** Approve for 1 month if the patient meets ALL of the following (A, B, and C):
- A) Patient is hospitalized; AND
 - B) Patient meets ONE of the following (i, ii, or iii):
 - i. Patient is a solid organ transplant recipient; OR
 - ii. Patient has had a hematopoietic stem cell transplant; OR
 - iii. Patient has cancer AND
 - C) The medication is prescribed by or in consultation with a critical care specialist, transplant physician, oncologist, infectious diseases physician, or pulmonologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of aerosolized ribavirin is not recommended in the following situations:

- 20. COVID-19 (Coronavirus Disease 2019).** Data are preliminary, additional study is needed.^{5,6} A Phase I, open-label, non-US (Greece, Brazil, and Mexico), non-randomized, two-arm study was conducted to evaluate the safety and efficacy of aerosolized ribavirin (as Virazole) in hospitalized adults with significant respiratory distress due to COVID-19 (n = 51).⁵ Patients received aerosolized ribavirin (100mg/mL for 30min or 50mg/mL for 60min) twice daily for up to 6 days. Improvement of one or more level in clinical status severity was observed in 31.4% (n = 16/51) and 78.4% (n = 40/51) of patients at end-of-treatment and Day 30, respectively. Of 21 patients who required a ventilator, 16 (76.2%) were able to discontinue ventilator use. One case series reported on five hospitalized adults with COVID-19 who received aerosolized ribavirin (100 mg/mL twice daily for 6 days) as part of a compassionate use program in Italy (patients were also managed in accordance with Italian treatment guidelines for COVID).⁶ All patients fully recovered. Ribavirin is not addressed as a recommended treatment modality in guidelines from the Infectious Diseases Society of America or the National Institutes of Health.^{7,8}
- 21.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Antivirals – Ribavirin (Oral Products) Prior Authorization Policy

- ribavirin tablets (generic)
- ribavirin capsules (generic)

REVIEW DATE: 06/19/2024

OVERVIEW

The ribavirin products included in this Prior Authorization policy are indicated for use **in combination with pegylated interferons or interferon for the treatment of chronic hepatitis C virus (HCV)** in adults and children with compensated disease. Ribavirin remains a component of some regimens for the management of HCV; however, there is no role for interferon (specifically non-pegylated interferon) in the management of HCV.² The specific indications vary slightly among the oral ribavirin products:

- Ribavirin capsules are indicated in combination with PegIntron® (peginterferon alfa-2b injection) or Intron A® (interferon alfa-2b injection) for the treatment of chronic HCV in patients ≥ 3 years of age with compensated liver disease.¹
- Ribavirin tablets are indicated in combination with Pegasys® (peginterferon alfa-2a) for the treatment of patients ≥ 5 years of age with chronic HCV with compensated liver disease who have not previously been treated with interferon alfa, and in adults with chronic HCV co-infected with human immunodeficiency virus.⁷

Ribavirin is an antiviral agent with direct antiviral activity in tissue culture against many RNA viruses.¹ Ribavirin increases the mutation frequency in the genomes of several viruses and ribavirin triphosphate inhibits HCV polymerase in a biochemical reaction.

According to the Centers for Disease Control and Prevention, oral ribavirin has been used off-label to treat other systemic viral infections including, but not limited to, Lassa fever^{5,6}, Nipah virus¹³, West Nile virus¹⁴, and Crimean Congo hemorrhagic fever.^{4,12} In addition, oral ribavirin has a place in therapy for the management of respiratory syncytial virus in transplant recipients.³

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of ribavirin. The intent of this Prior Authorization program is to ensure ribavirin is not used in the absence of pegylated interferon or a direct-acting antiviral for the treatment of HCV. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients being treated with ribavirin, as well as the monitoring required for adverse events and efficacy, approval requires ribavirin (for hepatitis C indications) to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: Automation is in place for the use of a pegylated interferon or a direct-acting antiviral for HCV in the past 130 days. This is used as a surrogate marker for HCV. If the criteria for prior use of a pegylated interferon or direct-acting antiviral for HCV are not met at the point-of-service, coverage will be determined by Prior Authorization criteria.

RECOMMENDED AUTHORIZATION CRITERIA

06/19/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Coverage of ribavirin is recommended in those who meet one of the following criteria:

FDA-Approved Indication

19. Hepatitis C Virus (HCV). Approve for 1 year if the patient meets BOTH of the following (A and B):

A) Patient meets ONE of the following (i or ii):

i. The medication is prescribed in combination with peginterferon alfa; OR

Note: Pegasys (pegylated interferon alfa-2a injection) is an example of a peginterferon alfa.

ii. The medication is prescribed in combination with a direct-acting antiviral for HCV; AND

Note: Examples of direct-acting antivirals for HCV include but are not limited to Epclusa (velpatasvir/sofosbuvir tablets), Sovaldi (sofosbuvir tablets/oral pellets), Harvoni (ledipasvir/sofosbuvir tablets/oral pellets), Zepatier (elbasvir/grazoprevir tablets).

B) The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, liver transplant physician, or infectious diseases physician.

Other Uses with Supportive Evidence

20. Other Systemic Viral Infections, Excluding COVID-19 (Coronavirus Disease 2019). Approve for 1 year.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of ribavirin is not recommended in the following situations:

22. COVID-19 (Coronavirus Disease 2019). Efficacy is not established.^{8,9} Ribavirin is not addressed as a treatment modality in guidelines from the Infectious Diseases Society of America or the National Institutes of Health.^{10,11}

23. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Attention Deficit Hyperactivity Disorder Non-Stimulant Medications Prior Authorization Policy

- Intuniv® (guanfacine extended-release tablets – Shire, generic)
- Kapvay® (clonidine hydrochloride extended-release tablets – Concordia, generic)
- Onyda™ XR (clonidine hydrochloride extended-release oral suspension – Tris)
- Strattera® (atomoxetine capsules – Eli Lilly, generic)
- Qelbree® (viloxazine extended-release capsules – Supernus)

REVIEW DATE: 08/07/2024

OVERVIEW

Atomoxetine capsules (Strattera, generic), guanfacine extended-release (ER) tablets (Intuniv, generic), clonidine ER tablets (Kapvay, generic), Onyda XR, and Qelbree are non-stimulant medications approved for the **treatment of attention deficit hyperactivity disorder (ADHD)**.¹⁻⁵

Atomoxetine capsules, a selective norepinephrine reuptake inhibitor, and Qelbree, a selective norepinephrine reuptake inhibitor, are indicated for the treatment of ADHD in children ≥ 6 years of age, adolescents, and adults.^{1,4} Guanfacine ER tablets, clonidine ER tablets, and Onyda XR, alpha agonists, are approved for use in children and adolescents 6 to 17 years of age with ADHD.^{2,3,5} Guanfacine ER tablets, clonidine ER tablets, and Onyda XR are indicated for use as monotherapy or as adjunctive therapy to stimulant medications.

Clinical Efficacy

Patients with pervasive developmental disorders who have symptoms of ADHD respond to ADHD medications at a reduced rate compared with typically developing peers and often with undesirable side effects.^{6,7} However, there is evidence to support use of these agents (e.g., stimulants, atomoxetine capsules, guanfacine ER tablets, and clonidine ER tablets) in this patient population.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of atomoxetine capsules (Strattera, generic), clonidine ER tablets (Kapvay, generic), guanfacine ER tablets (Intuniv, generic), Onyda XR, and Qelbree. All approvals are provided for the duration noted below.

Automation: An age edit is in place such that a patient 6 to 18 years of age will be approved at the point of service. For a patient < 6 or > 18 years of age, coverage will be determined by Prior Authorization criteria.

RECOMMENDED AUTHORIZATION CRITERIA

- I. Coverage of atomoxetine capsules (Strattera, generic), clonidine ER tablets (Kapvay, generic), Onyda XR, or guanfacine ER tablets (Intuniv, generic) is recommended in those who meet one of the following criteria:

08/07/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

FDA-Approved Indication

- 7. Attention Deficit Hyperactivity Disorder.** Approve for 1 year if the patient is ≥ 6 years of age.

Other Uses with Supportive Evidence

- 8. Pervasive Developmental Disorders (e.g., autism spectrum disorder, Asperger's disorder).** Approve for 1 year if the patient has symptoms of attention deficit hyperactivity disorder (e.g., inattention, hyperactivity).

- II. Coverage of Qelbree is recommended in those who meet the following criteria:

FDA-Approved Indication

- 1. Attention Deficit Hyperactivity Disorder.** Approve for 1 year if the patient is ≥ 6 years of age.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of atomoxetine capsules (Strattera, generic), clonidine ER tablets (Kapvay, generic), guanfacine ER tablets (Intuniv, generic), or Qelbree is not recommended in the following situations:

- 29. Binge-Eating Disorder.** In one 10-week, placebo-controlled study in outpatients with binge-eating disorder ($n = 40$), atomoxetine was associated with a significantly greater reduction in binge-eating episode frequency vs. placebo.⁸ Additional studies with atomoxetine are needed. There are no data with guanfacine ER tablets, clonidine ER tablets, or Qelbree.
- 30. Depression without Attention Deficit/Hyperactivity Disorder.** Limited information is available on the use of atomoxetine for the treatment of major depressive disorder. In three case reports and one case series in 15 patients with depressive disorders, adding atomoxetine to a selective serotonin reuptake inhibitor resulted in further improvement.^{9,10} However, in a published controlled trial, patients with major depressive disorder (without ADHD) [$n = 276$] were treated with sertraline at doses up to 200 mg/day.¹¹ Patients who continued to experience depressive symptoms ($n = 146$) were then randomly assigned to either treatment with atomoxetine 40 to 120 mg/day or placebo for an additional 8 weeks. There was no difference between the atomoxetine/sertraline and placebo/sertraline treatment groups in mean change in depressive symptom severity or in the number of patients whose depressive symptoms remitted (40.3% vs. 37.8%, respectively; $P = 0.865$). Atomoxetine did not improve clinically significant depression in patients with Parkinson disease ($n = 55$) in one study.¹² There are no data with guanfacine ER tablets, clonidine ER tablets, or Qelbree.
- 31. Fibromyalgia.** In case reports, atomoxetine was effective in reducing fatigue and pain in fibromyalgia syndrome.¹³ Well-controlled trials with atomoxetine are needed to establish safety and efficacy. There are no data with guanfacine ER tablets, clonidine ER tablets, or Qelbree.
- 32. Improve Cognitive Function (or Neuroenhancement).** The use of prescription medication to augment cognitive or affective function in otherwise healthy individuals (also known as neuroenhancement) is increasing in adult and pediatric populations.²¹ A 2013 Ethics, Law, and Humanities Committee position paper, endorsed by the American Academy of Neurology, indicates that based on currently available data and the balance of ethics issues, neuroenhancement in children and adolescents without a diagnosis of a neurologic disorder is not justifiable. The prescription of neuroenhancements is inadvisable due to numerous social, developmental, and professional integrity

issues. Several studies have evaluated atomoxetine for cognitive function in various patient populations, including patients with Huntington disease¹⁴, Alzheimer's disease¹⁵, schizophrenia^{16,17}, and Parkinson's disease.¹⁸ However, atomoxetine has not demonstrated clinical benefit.

- 33. Long-Term Combination Therapy (i.e., > 2 months) with atomoxetine (Strattera, generic) and Central Nervous System (CNS) Stimulants used for the Treatment of Attention Deficit/Hyperactivity Disorder (e.g., mixed amphetamine salts ER capsules [Adderall XR, generic], methylphenidate ER tablets, methylphenidate immediate-release tablets).** Currently, data do not support using atomoxetine and CNS stimulant medications concomitantly.^{19,20} Short-term drug therapy (2 months or less) with both atomoxetine and CNS stimulant medications is allowed for transitioning the patient to only one drug. Guanfacine ER tablets, clonidine ER tablets, and Onyda XR are indicated for use as monotherapy or as adjunctive therapy to CNS stimulant medications; therefore, long-term combination therapy with either agent and CNS stimulants is appropriate.^{2,3,5} Qelbree labeling does not address combination use with CNS stimulants at this time.⁴
- 34. Nocturnal Enuresis.** In case reports, children with ADHD and other comorbid psychiatric diagnoses who had nocturnal enuresis and were treated with atomoxetine had resolution of their enuresis.²² In one controlled trial in pediatric patients (n = 87) with nocturnal enuresis, atomoxetine increased the average number of dry nights per week by 1.47 vs. 0.60 for placebo (P = 0.01).²³ Additional controlled trials with atomoxetine are needed. Data with guanfacine ER tablets, clonidine ER tablets, or Qelbree are lacking.
- 35. Weight Loss.** In one 12-week, placebo-controlled study in obese women (n = 30), atomoxetine resulted in a mean -3.7% loss vs. 0.2% gain with placebo when combined with a hypocaloric diet (500 kcal/day deficit).²⁴ Atomoxetine did not demonstrate efficacy for weight reduction in patients with schizophrenia (n = 37) treated with antipsychotics (clozapine or olanzapine).²⁵ Additional studies are needed.
- 36.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Attention Deficit Hyperactivity Disorder Stimulant Medications Prior Authorization Policy

REVIEW DATE: 08/07/2024

08/07/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

OVERVIEW

The central nervous system (CNS) stimulant medications in this policy are indicated for the following uses:^{1-24,43,44,48-54}

- **Attention deficit hyperactivity disorder (ADHD)**, treatment. All of the stimulant medications in this policy are indicated for the treatment of ADHD.
- **Binge eating disorder**, treatment. Vyvanse is the only stimulant medication indicated for the treatment of binge eating disorder.
- **Narcolepsy**, treatment. Several methylphenidate and amphetamine-containing products are also indicated for the treatment of narcolepsy.
- **Exogenous obesity**, treatment. Evekeo is indicated as adjunctive therapy for the short-term (i.e., a few weeks) treatment of exogenous obesity.

Dextroamphetamine sulfate tablets, Zenzedi, and Adderall (generic) are indicated in patients ≥ 3 years of age; the other products are indicated in patients ≥ 6 years of age, except for Mydayis which is indicated in patients ≥ 13 years of age.^{1,2,6,19,43} Adderall XR (generic), Adzenys ER, Adzenys XR-ODT, Concerta (generic), Mydayis, Vyvanse, Xelstrym, and several methylphenidate products are indicated for use in adults with ADHD.^{2,5,9,24,43,48,54} Jornay PM is the only stimulant taken in the evening.⁴⁹

Other Uses with Supportive Evidence

Idiopathic hypersomnia: A condition similar to narcolepsy, idiopathic hypersomnia is characterized by constant or recurrent daytime sleepiness with no other cause of sleepiness, prolonged nocturnal sleep, difficulty awakening with sleep drunkenness, and long unrefreshing naps with no cataplexy.²⁹⁻³²

Guidelines

Narcolepsy and other hypersomnias: The practice parameters from the American Academy of Sleep Medicine for the treatment of central disorders of hypersomnolence (2021) state that dextroamphetamine and methylphenidate, in addition to other wakefulness-promoting agents, are effective for treatment of daytime sleepiness due to narcolepsy.²⁵ The parameters also state that methylphenidate, in addition to other agents, may be effective for the treatment of daytime sleepiness due to idiopathic hypersomnia. As there may be underlying causes/behaviors associated with excessive daytime sleepiness, a sleep specialist physician has the training to correctly recognize and diagnose this condition.

Major depressive disorder (MDD): The 2010 American Psychiatric Association practice guidelines for the treatment of patients with MDD state that many clinicians find augmentation of antidepressants with low doses of stimulants such as methylphenidate or dextroamphetamine may help ameliorate otherwise suboptimally responsive depression, although not all clinical trials have shown benefits from this strategy.²⁶ There are no clear guidelines regarding the length of time stimulants should be co-administered. A 16-week randomized, double-blind, placebo-controlled trial in older outpatients with major depression (mean age of 70 years) [n = 143] found that combined treatment with citalopram and methylphenidate demonstrated an enhanced clinical response profile in mood and wellbeing, as well as a higher rate of remission, compared with either drug alone.⁴⁵

Cancer-related fatigue: The National Comprehensive Cancer Network (NCCN) guidelines on cancer-related fatigue (version 2.2024 – October 30, 2023) state to consider use of psychostimulants (i.e., methylphenidate) in consideration of other modifiable causes.²⁷ The NCCN guidelines on adult cancer pain (version 2.2024 – March 11, 2024) state that sedation may hinder the achievement of dose titration of opioids to levels that provide adequate analgesia.²⁸ If opioid-induced sedation develops, it may be managed by administration of a psychostimulant, such as methylphenidate, dextroamphetamine, modafinil, armodafinil, or by adding caffeine. A meta-analysis of treatments for fatigue associated with palliative care

showed a superior effect for methylphenidate in cancer-related fatigue.⁴⁶ A review of methylphenidate for cancer-related fatigue found a small but significant improvement in fatigue over placebo (P = 0.005).⁴⁷

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of ADHD stimulant medications in adults. Only patients ≥ 18 years of age will be required to meet the Prior Authorization criteria below. All approvals are provided for the duration noted below.

Automation: An age edit is in place such that a patient less than 18 years of age will be approved at the point of service. For a patient ≥ 18 years of age, coverage will be determined by Prior Authorization criteria.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of ADHD stimulant medications is recommended in those who meet one of the following criteria:

FDA-Approved Indications

9. **Attention Deficit Hyperactivity Disorder.** Approve for 1 year.
2. **Binge Eating Disorder.** Approve only Vyvanse (brand or generic) for 1 year if the patient is ≥ 18 years of age.
3. **Narcolepsy.** Approve for 1 year.

Other Uses with Supportive Evidence

4. **Depression, Adjunctive/Augmentation Treatment in an Adult.** Approve for 1 year if the patient is concurrently receiving other medication therapy for depression.
Note: Examples of medications for the treatment of depression include selective serotonin reuptake inhibitors.
5. **Fatigue associated with Cancer and/or its Treatment.** Approve for 1 year.
6. **Idiopathic Hypersomnolence.** Approve for 1 year if the diagnosis is confirmed by a sleep specialist physician or at an institution that specializes in sleep disorders (i.e., sleep center).

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of ADHD stimulant medications is not recommended in the following situations:

1. **Fatigue Associated with Multiple Sclerosis.** There are no published studies supporting this use. In addition, neither recent review articles nor the 2021 practice parameters for the treatment of narcolepsy and other hypersomnias of central origin mention stimulants (only modafinil). Practice parameters for the treatment of narcolepsy and other hypersomnias of central origin, updated in 2021, state that modafinil may be effective for the treatment of daytime sleepiness due to multiple sclerosis.²⁵ Agents that have been studied for the treatment of fatigue due to multiple sclerosis include amantadine, modafinil, and methylphenidate; these medications were not superior to placebo for this use.⁴¹

37. **Long-Term Combination Therapy (i.e., > 2 months) with atomoxetine capsules (Strattera, generic) and Central Nervous System (CNS) Stimulants for the treatment of Attention Deficit/Hyperactivity Disorder (e.g., mixed amphetamine salts extended-release capsules [Adderall XR®, generics], methylphenidate extended-release tablets, methylphenidate immediate-release tablets).** Currently, data do not support using Strattera and CNS stimulant medications concomitantly.⁴² Short-term drug therapy (≤ 2 months) with both atomoxetine and CNS stimulant medications is allowed for transitioning the patient to only one drug. Guanfacine extended-release tablets (Intuniv®, generic) and clonidine extended-release tablets (Kapvay®, generic) are indicated for use as monotherapy, or as adjunctive therapy to CNS stimulant medications; therefore, long-term combination therapy with either agent and CNS stimulants is appropriate.^{33,34}
38. **Neuroenhancement.** The use of prescription medication to augment cognitive or affective function in otherwise healthy individuals (also known as neuroenhancement) is increasing in adult and pediatric populations.³⁵ A 2013 Ethics, Law, and Humanities Committee position paper, endorsed by the American Academy of Neurology indicates that based on available data and the balance of ethics issues, neuroenhancement in legally and developmentally non-autonomous children and adolescents without a diagnosis of a neurologic disorder is not justifiable. In nearly autonomous adolescents, the fiduciary obligation of the physician may be weaker, but the prescription of neuroenhancements is inadvisable due to numerous social, developmental, and professional integrity issues.
39. **Weight Loss.** Of the CNS stimulants, only amphetamine sulfate tablets (e.g., Evekeo tablets) are indicated for exogenous obesity, as a short-term (i.e., a few weeks) adjunct in a regimen of weight reduction based on caloric restriction, for patients in whom obesity is refractory to alternative therapy (e.g., repeated diets, group programs, and other drugs).²⁰ However, guidelines on the management of obesity do not address or recommend use of amphetamine (or any other CNS stimulants).³⁶⁻⁴⁰
40. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Benign Prostatic Hyperplasia – Entadfi Prior Authorization Policy

- Entadfi™ (finasteride and tadalafil capsules – Veru)

REVIEW DATE: 12/11/2024

OVERVIEW

Entadfi, a combination of finasteride 5 mg (a 5-alpha-reductase inhibitor) and tadalafil 5 mg (a phosphodiesterase 5 inhibitor), is indicated to initiate treatment of the signs and symptoms of **benign prostatic hyperplasia** in men with an enlarged prostate for up to 26 weeks.¹

Entadfi has a limitation of use which states the medication is not recommended for more than 26 weeks because the incremental benefit of tadalafil decreases from 4 weeks until 26 weeks, and then the incremental benefit beyond 26 weeks is unknown.¹ This is the same limitation of use included in tadalafil labeling and it applies to situations in which tadalafil is used with finasteride to initiate benign prostatic hyperplasia treatment.²

Guidelines

The American Urological Association guidelines on the management of lower urinary tract symptoms attributed to benign prostatic hyperplasia (2023) note that 5-alpha reductase inhibitors (alone or in combination with an alpha blocker) are recommended as a treatment option to prevent progression of lower urinary tract symptoms/benign prostatic hyperplasia.³ Guidelines note that clinicians may offer the combination of low-dose 5 mg tadalafil with an alpha blocker; however, there is little benefit with the combination. Regarding tadalafil, it is noted that in patients with benign prostatic hyperplasia, irrespective of a comorbid erectile dysfunction, daily 5 mg tadalafil should be discussed as a treatment option.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Entadfi. All approvals are provided for the duration noted below.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Entadfi is recommended in those who meet the following criteria:

FDA-Approved Indication

21. Benign Prostatic Hyperplasia. Approve for 6 months.

12/11/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Entadfi is not recommended in the following situations:

24. **Erectile Dysfunction without Benign Prostatic Hyperplasia.** Entadfi is not indicated for erectile dysfunction in patient without benign prostatic hyperplasia.¹
25. **Alopecia.** Entadfi is not indicated for alopecia.¹ Finasteride 1 mg tablets are indicated for the treatment of male pattern hair loss (androgenetic alopecia).⁴
26. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Bone Modifiers – Evenity Prior Authorization Policy

- Evenity® (romosozumab-aqqg subcutaneous injection – Amgen)

REVIEW DATE: 10/23/2024

OVERVIEW

Evenity, a sclerostin inhibitor, is indicated for the treatment of **osteoporosis** in postmenopausal women at high risk for fracture, defined as a of osteoporotic fracture, or multiple risk factors for fracture; or patients who have failed or are intolerant to other available osteoporosis therapy.¹ It is recommended to adequately supplement with calcium and vitamin D during treatment with Evenity. According to the Evenity prescribing information, the anabolic effect of Evenity wanes after 12 monthly doses of therapy. Therefore, limit the duration of use to 12 monthly doses. If osteoporosis therapy remains warranted, continued therapy with an anti-resorptive therapy (e.g., alendronate) should be considered. Evenity should be administered by a healthcare provider.

Guidelines

Evenity is cited in guidelines that discuss the management of postmenopausal osteoporosis.^{2,3}

- **Postmenopausal Osteoporosis:** The Endocrine Society (2020) issued a guideline update regarding the pharmacological management of osteoporosis in postmenopausal women which addressed Evenity.² In postmenopausal women with osteoporosis at very high risk of fractures such as patients with severe osteoporosis (i.e., low T-score < -2.5 and fractures) or multiple fractures, Evenity therapy is recommended for up to 1 year for the reduction of vertebral, hip, and nonvertebral fractures. The recommended dose is 210 mg monthly by subcutaneous injection for 12 months. In postmenopausal women with osteoporosis who have completed a course of Evenity, antiresorptive osteoporosis therapy is recommended to maintain bone density gains and reduce fracture risk.
- **Treatment and Prevention of Osteoporosis:** In 2022, the Bone Health and Osteoporosis Foundation updated a guideline for the prevention and treatment of osteoporosis (2022).³ In the 12-month FRAME trial involving women with postmenopausal osteoporosis, Evenity, compared with placebo, reduced the risk of new vertebral fracture by 73% and clinical fractures by 36%. In the ARCH trial, high-risk postmenopausal women experienced significantly fewer fractures when given Evenity compared with alendronate for 12 months (48% fewer new vertebral fractures, 19% fewer non-vertebral fractures, and 38% fewer hip fractures). However, the Boxed Warning that Evenity has regarding an increased risk for myocardial infarction, stroke, and cardiovascular death was concerning.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Evenity. Coverage is limited to 12 monthly doses during the therapy course.

Automation: None.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Evenity is recommended in those who meet the following criteria:

FDA-Approved Indication

1. Osteoporosis Treatment of a Postmenopausal Patient. Approve for 1 year if the patient meets ALL of the following (A, B, and C):

A) Patient meets ONE of the following (i, ii, or iii):

- i.** Patient has had a T-score (current or at any time in the past) at or below -2.5 at the lumbar spine, femoral neck, total hip, and/or 33% (one-third) radius (wrist); OR
- ii.** Patient has had an osteoporotic fracture or a fragility fracture; OR
- iii.** Patient meets BOTH of the following (a and b):

a) Patient has low bone mass; AND

Note: Examples of a low bone mass include a T-score (current or at any time in the past) between -1.0 and -2.5 at the lumbar spine, femoral neck, total hip, and/or 33% (one third) radius (wrist).

b) According to the prescriber, the patient is at high risk for fracture; AND

B) The patient meets ONE of the following (i, ii, iii, or iv):

i. Patient has tried ibandronate injection (Boniva IV) or zoledronic acid injection (Reclast); OR

ii. Patient has tried at least one oral bisphosphonate or oral bisphosphonate-containing product and meets ONE of the following (a or b):

Note: Examples of oral bisphosphonate products include Fosamax (alendronate tablets and oral solution), Fosamax Plus D (alendronate/cholecalciferol tablets), Actonel (risedronate tablets), Atelvia (risedronate delayed-release tablets), and Boniva (ibandronate tablets).

a) According to the prescriber, the patient has experienced inadequate efficacy to oral bisphosphonate therapy after a trial duration of 12 months; OR

Note: Examples of inadequate efficacy are ongoing and significant loss of bone mineral density (BMD), lack of a BMD increase, and/or an osteoporotic fracture or a fragility fracture.

b) Patient has experienced significant intolerance to an oral bisphosphonate; OR

Note: Examples of significant intolerance include severe gastrointestinal related adverse events, severe musculoskeletal related adverse events, or a femoral fracture.

iii. Patient cannot take an oral bisphosphonate due to ONE of the following circumstances (a, b, or c):

a) Patient cannot swallow or has difficulty swallowing; OR

b) Patient cannot remain in an upright position post oral bisphosphonate administration; OR

c) Patient has a pre-existing gastrointestinal medical condition; OR

Note: Examples of pre-existing gastrointestinal medical conditions include esophageal lesions, esophageal ulcers, or abnormalities of the esophagus that delay esophageal emptying (stricture, achalasia).

iv. Patient meets ONE of the following (a or b):

a) According to the prescriber, the patient has severe renal impairment or chronic kidney disease; OR

Note: An example of severe renal impairment is a creatinine clearance < 35 mL/minute.

b) Patient has had an osteoporotic fracture or a fragility fracture; AND

C) Patient has received no more than 12 monthly doses during this therapy course.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Evenity is not recommended in the following situations:

- 41. Osteoporosis Prevention.** Evenity is not indicated for the prevention of osteoporosis.
- 42. Concurrent Use with Other Medications for Osteoporosis.**
Note: Examples of medications for osteoporosis that Evenity should not be given with include oral bisphosphonates (e.g., alendronate, risedronate, ibandronate), intravenous bisphosphonates (zoledronic acid injection [Reclast], intravenous ibandronate), Prolia (denosumab subcutaneous injection), Forteo (teriparatide subcutaneous injection, generic), Tymlos (abaloparatide subcutaneous injection), and calcitonin nasal spray (Miacalcin/Fortical). However, this does NOT exclude use of calcium and/or vitamin D supplements in combination with Evenity.
- 43.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Bone Modifiers – Ibandronate Intravenous Prior Authorization Policy

- ibandronate intravenous infusion – generic

REVIEW DATE: 03/13/2024

OVERVIEW

Ibandronate injection is indicated for the treatment of **osteoporosis** in postmenopausal women.¹

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of ibandronate injection. All approvals are provided for the duration noted below.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of ibandronate injection is recommended in those who meet the following criteria:

FDA-Approved Indication

2. Osteoporosis – Treatment for a Postmenopausal Patient. Approve for 1 year if the patient meets BOTH of the following (A and B):

A) Patient meets ONE of the following (i, ii, or iii):

iv. Patient has had a T-score (current or at any time in the past) at or below -2.5 at the lumbar spine, femoral neck, total hip, and/or 33% (one-third) radius (wrist); OR

v. Patient has had an osteoporotic fracture or a fragility fracture; OR

vi. Patient meets BOTH of the following (a and b):

a) Patient has low bone mass; AND

Note: An example of low bone mass includes a T-score (current or at any time in the past) between -1.0 and -2.5 at the lumbar spine, femoral neck, total hip, and/or 33% (one-third) radius (wrist).

b) According to the prescriber, patient is at high risk for fracture; AND

B) Patient meets ONE of the following (i, ii, iii, or iv):

i. Patient has tried ibandronate injection (Boniva) or zoledronic acid injection (Reclast); OR

ii. Patient has tried at least one oral bisphosphonate or oral bisphosphonate-containing product and meets ONE of the following (a or b):

Note: Examples of oral bisphosphonate products include Fosamax (alendronate tablets and oral solution), Fosamax Plus D (alendronate/cholecalciferol tablets), Actonel (risedronate tablets), Atelvia (risedronate delayed-release tablets), and Boniva (ibandronate tablets).

a) According to the prescriber, patient has experienced inadequate efficacy to oral bisphosphonate therapy after a trial duration of 12 months; OR

Note: Examples of inadequate efficacy are ongoing and significant loss of bone mineral density (BMD), lack of a BMD increase, and/or an osteoporotic fracture or a fragility fracture.

03/13/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- b) Patient has experienced significant intolerance to an oral bisphosphonate; OR
Note: Examples of significant intolerance include severe gastrointestinal related adverse events, severe musculoskeletal related adverse events, or a femoral fracture.
 - iii. Patient cannot take an oral bisphosphonate due to ONE of the following (a, b, or c):
 - a) Patient cannot swallow or has difficulty swallowing; OR
 - b) Patient cannot remain in an upright position post oral bisphosphonate administration; OR
 - c) Patient has a pre-existing gastrointestinal medical condition in which intravenous bisphosphonate therapy may be warranted; ORNote: Examples of pre-existing gastrointestinal medical conditions include esophageal lesions, esophageal ulcers, or abnormalities of the esophagus that delay esophageal emptying (stricture, achalasia).
- iv. Patient has had an osteoporotic fracture or a fragility fracture.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of ibandronate injection is not recommended in the following situations:

- 44. **Osteoporosis Prevention.** Ibandronate injection is not indicated for the prevention of osteoporosis and supporting data are limited.
- 45. **Concurrent Use of Ibandronate Injection with Other Medications for Osteoporosis.**
Note: Examples of medications for osteoporosis that ibandronate injection should not be given with include oral bisphosphonates (e.g., alendronate, risedronate, ibandronate), other intravenous bisphosphonates (e.g., zoledronic acid injection [Reclast]), Prolia (denosumab subcutaneous injection), Evenity (romosozumab-aqqg subcutaneous injection), Forteo (teriparatide subcutaneous injection), Tymlos (abaloparatide subcutaneous injection), and calcitonin nasal spray. However, this does NOT exclude use of calcium and/or vitamin D supplements in combination with ibandronate injection.
- 46. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Bone Modifiers – Prolia Prior Authorization Policy

- Prolia® (denosumab subcutaneous injection – Amgen)

REVIEW DATE: 10/23/2024

OVERVIEW

Prolia, a receptor activator of nuclear factor kappa-B ligand inhibitor, is indicated for the following uses:¹

- **Bone loss (treatment to increase bone mass), in men with nonmetastatic prostate cancer** at high risk for fracture receiving androgen deprivation therapy.
- **Bone loss (treatment to increase bone mass), in women with breast cancer** at high risk for fracture receiving adjuvant aromatase inhibitor therapy.
- **Glucocorticoid-induced osteoporosis** (treatment), in men and women at high risk of fracture who are either initiating or continuing systemic glucocorticoids in a daily dosage equivalent to 7.5 mg or greater of prednisone and expected to remain on glucocorticoids for at least 6 months.
- **Osteoporosis**, treatment of **postmenopausal women** at high risk of fracture.
- **Osteoporosis**, treatment to **increase bone mass in men** at high risk for fracture.

In general, high risk of fractures is defined as a history of osteoporotic fracture, multiple risk factors for fracture, or patients who have failed or are intolerant to other available osteoporosis therapy.¹ Of note, denosumab subcutaneous injection is also available under the brand name Xgeva®, and is indicated for the prevention of skeletal-related events in patients with multiple myeloma, as well as in patients with bone metastases from solid tumors, giant cell tumor of bone, and hypercalcemia of malignancy.²

Dosing Information

For all indications, the dose is 60 mg once every 6 months as a subcutaneous injection.¹

Guidelines

Several guidelines address Prolia.

- **Breast Cancer/Prostate Cancer:** The National Comprehensive Cancer Network guidelines for breast cancer (version 4.2024 – July 3, 2024)³ and prostate cancer (version 4.2024 – May 17, 2024)⁴ note that if patients are receiving agents that impact bone mineral density (BMD), bisphosphonates (oral/intravenous), as well as Prolia, should be considered to maintain or improve BMD and/or reduce the risk of fractures.
- **Glucocorticoid-Induced Osteoporosis (GIO):** In 2022, the American College of Rheumatology published guidelines for the prevention and treatment of GIO.⁵ In various clinical scenarios, oral bisphosphonates are preferred, followed by intravenous bisphosphonates (e.g., zoledronic acid intravenous infusion [Reclast]). Prolia has a role in higher-risk patients.
- **Postmenopausal Osteoporosis:** Prolia is prominently featured in guidelines for postmenopausal osteoporosis by the Endocrine Society (2019)⁶ and the American Association of Clinical Endocrinologists and the American College of Endocrinology (2020).⁷ Prolia is one of several agents cited as an alternative for patients at high risk for fractures. The Bone Health and Osteoporosis Foundation clinician's guide for prevention and treatment of osteoporosis (2022) cites Prolia as robustly reducing vertebral and non-vertebral fractures in studies involving women with postmenopausal osteoporosis.⁸

Safety

Prolia has a Boxed Warning regarding hypocalcemia in patients with advanced kidney disease.¹ Patients with advanced chronic kidney disease are at greater risk of severe hypocalcemia following Prolia administration. Severe hypocalcemia resulting in hospitalization, life-threatening events, and fatal cases have been reported. The presence of chronic kidney disease mineral and bone disorder (CKD-MBD) greatly increases the risk of hypocalcemia. Before starting Prolia in patients with advanced chronic kidney disease, evaluate for the presence of CKD-MBD. Treatment with Prolia in these patients should be supervised by a healthcare provider with expertise in the diagnosis and management of CKD-MBD.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Prolia. All approvals are provided for 1 year in duration. In the approval indication, as appropriate, an asterisk (*) is noted next to the specified gender. In this context, the specified gender is defined as follows: men are defined as individuals with the biological traits of a man, regardless of the individual's gender identity or gender expression.

Automation: Smart Coverage Review uses patient claims history to answer Prior Authorization questions regarding medication history of Boniva® (ibandronate intravenous infusion) or Reclast® (zoledronic acid intravenous infusion). A 2-year look back period will be used to check claims history and automate for use of either agent (Boniva intravenous or Reclast). If not in claims, medication can be obtained through Prior Authorization criteria. For all reviews, other Prior Authorization criteria listed below will also be applied.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Prolia is recommended in those who meet one of the following criteria:

FDA-Approved Indications

16. Bone Loss (Treatment to Increase Bone Mass) in Patients with Breast Cancer at High Risk for Fracture Receiving Adjuvant Aromatase Inhibitor Therapy. Approve for 1 year if the patient meets BOTH of the following (A and B):

- A) Patient has breast cancer that is not metastatic to bone; AND
- B) Patient is receiving aromatase inhibitor therapy.

Note: Examples of aromatase inhibitor therapy are anastrozole, letrozole, or exemestane.

17. Bone Loss (Treatment to Increase Bone Mass) in Patients with Nonmetastatic Prostate Cancer at High Risk for Fracture Receiving Androgen Deprivation Therapy. Approve for 1 year if the patient meets BOTH of the following (A and B):

- A) Patient has prostate cancer that is not metastatic to bone; AND
- B) Patient meets ONE of the following (i or ii):

- i. Patient is receiving androgen deprivation therapy; OR

Note: Examples of androgen deprivation therapy are Lupron Depot (leuprolide depot suspension injection), Eligard (leuprolide acetate suspension injectable), Trelstar (triptorelin pamoate suspension injection), and Zoladex (goserelin implant).

- ii. Patient has undergone bilateral orchiectomy.

18. Glucocorticoid-Induced Osteoporosis – Treatment. Approve for 1 year if the patient meets BOTH of the following (A and B):

- A) Patient is either initiating or continuing systemic glucocorticoids; AND

Note: An example of a systemic glucocorticoid is prednisone.

- B) Patient meets ONE of the following (i, ii, iii, or iv):**
- i.** Patient has tried zoledronic acid intravenous infusion (Reclast); OR
 - ii.** Patient has tried at least one oral bisphosphonate or oral bisphosphonate-containing product and meets ONE of the following (a or b):
Note: Examples of oral bisphosphonate products include Fosamax (alendronate tablets and oral solution), Fosamax Plus D (alendronate/cholecalciferol tablets), Actonel (risedronate tablets), Atelvia (risedronate delayed-release tablets), and Boniva (ibandronate tablets).
 - a)** According to the prescriber, patient has experienced inadequate efficacy to oral bisphosphonate therapy after a trial duration of 12 months; OR
Note: Examples of inadequate efficacy are ongoing and significant loss of bone mineral density (BMD), lack of a BMD increase, and/or an osteoporotic fracture or a fragility fracture.
 - b)** Patient has experienced significant intolerance to an oral bisphosphonate; OR
Note: Examples of significant intolerance include severe gastrointestinal related adverse events and/or severe musculoskeletal related adverse events.
 - iii.** Patient cannot take an oral bisphosphonate due to ONE of the following (a, b, or c):
 - a)** Patient cannot swallow or has difficulty swallowing; OR
 - b)** Patient cannot remain in an upright position post oral bisphosphonate administration; OR
 - c)** Patient has a pre-existing gastrointestinal medical condition; OR
Note: Examples of pre-existing gastrointestinal medical conditions include esophageal lesions, esophageal ulcers, or abnormalities of the esophagus that delay esophageal emptying (stricture, achalasia).
 - iv.** Patient meets ONE of the following (a or b):
 - a)** Patient meets BOTH of the following [(1) and (2)]:
 - (1)** According to the prescriber, the patient has severe renal impairment or chronic kidney disease; AND
Note: An example of severe renal impairment is a creatinine clearance < 35 mL/minute.
 - (2)** Patient has been evaluated for the presence of chronic kidney disease mineral and bone disorder to reduce the risk of Prolia-induced hypocalcemia; OR
 - b)** Patient has had an osteoporotic fracture or a fragility fracture.

19. Osteoporosis Treatment for a Postmenopausal Patient. Approve for 1 year if the patient meets BOTH of the following (A and B):

- A) Patient meets ONE of the following (i, ii, or iii):**
- i.** Patient has had a T-score (current or at any time in the past) at or below -2.5 at the lumbar spine, femoral neck, total hip, and/or 33% (one-third) radius (wrist); OR
 - ii.** Patient has had an osteoporotic fracture or a fragility fracture; OR
 - iii.** Patient meets BOTH of the following (a and b):
 - a)** Patient has low bone mass; AND
Note: An example of low bone mass includes a T-score (current or at any time in the past) between -1.0 and -2.5 at the lumbar spine, femoral neck, total hip, and/or 33% (one-third) radius (wrist).
 - b)** According to the prescriber, patient is at high risk for fracture; AND
- B) Patient meets ONE of the following (i, ii, iii, or iv):**
- i.** Patient has tried ibandronate intravenous injection (Boniva) or zoledronic acid intravenous infusion (Reclast); OR
 - ii.** Patient has tried at least one oral bisphosphonate or oral bisphosphonate-containing product and meets ONE of the following (a or b):

Note: Examples of oral bisphosphonate products include Fosamax (alendronate tablets and oral solution), Fosamax Plus D (alendronate/cholecalciferol tablets), Actonel (risedronate tablets), Atelvia (risedronate delayed-release tablets), and Boniva (ibandronate tablets).

- a) According to the prescriber, patient has experienced inadequate efficacy to oral bisphosphonate therapy after a trial duration of 12 months; OR

Note: Examples of inadequate efficacy are ongoing and significant loss of bone mineral density (BMD), lack of a BMD increase, and/or an osteoporotic fracture or a fragility fracture.

- b) Patient has experienced significant intolerance to an oral bisphosphonate; OR

Note: Examples of significant intolerance include severe gastrointestinal related adverse events and/or severe musculoskeletal related adverse events.

- iii. Patient cannot take an oral bisphosphonate due to ONE of the following (a, b, or c):

- a) Patient cannot swallow or has difficulty swallowing; OR

- b) Patient cannot remain in an upright position post oral bisphosphonate administration; OR

- c) Patient has a pre-existing gastrointestinal medical condition; OR

Note: Examples of pre-existing gastrointestinal medical conditions include esophageal lesions, esophageal ulcers, or abnormalities of the esophagus that delay esophageal emptying (stricture, achalasia).

- iv. Patient meets ONE of the following (a or b):

- a) Patient meets BOTH of the following [(1) and (2)]:

- (1) According to the prescriber, the patient has severe renal impairment or chronic kidney disease; AND

Note: An example of severe renal impairment is a creatinine clearance < 35 mL/minute.

- (2) Patient has been evaluated for the presence of chronic kidney disease mineral and bone disorder to reduce the risk of Prolia-induced hypocalcemia; OR

- b) Patient has had an osteoporotic fracture or a fragility fracture.

20. Osteoporosis Treatment (to Increase Bone Mass) for Men*. Approve for 1 year if the patient meets BOTH of the following (A and B):

- A) Patient meets ONE of the following (i, ii, or iii):

- i. Patient has had a T-score (current or at any time in the past) at or below -2.5 at the lumbar spine, femoral neck, total hip, and/or 33% (one-third) radius (wrist); OR

- ii. Patient has had an osteoporotic fracture or a fragility fracture; OR

- iii. Patient meets BOTH of the following (a and b):

- a) Patient has low bone mass; AND

Note: An example of low bone mass includes a T-score (current or at any time in the past) between -1.0 and -2.5 at the lumbar spine, femoral neck, total hip, and/or 33% (one-third) radius (wrist).

- b) According to the prescriber, patient is at high risk of fracture; AND

- B) Patient meets ONE of the following (i, ii, iii, or iv):

- i. Patient has tried zoledronic acid intravenous infusion (Reclast); OR

- ii. Patient has tried at least one oral bisphosphonate or oral bisphosphonate-containing product and meets ONE of the following (a or b):

Note: Examples of oral bisphosphonate products include Fosamax (alendronate tablets and oral solution), Fosamax Plus D (alendronate/cholecalciferol tablets), Actonel (risedronate tablets), Atelvia (risedronate delayed-release tablets), and Boniva (ibandronate tablets).

- a) According to the prescriber, patient has experienced inadequate efficacy to oral bisphosphonate therapy after a trial duration of 12 months; OR

Note: Example of inadequate efficacy are ongoing and significant loss of bone mineral density (BMD), lack of a BMD increase, and/or an osteoporotic fracture or a fragility fracture.

- b) Patient has experienced significant intolerance to an oral bisphosphonate; OR

Note: Examples of significant intolerance include severe gastrointestinal related adverse events and/or severe musculoskeletal related adverse events.

- iii. Patient cannot take an oral bisphosphonate due to ONE of the following (a, b, or c):

- a) Patient cannot swallow or has difficulty swallowing; OR

- b) Patient cannot remain in an upright position post oral bisphosphonate administration; OR

- c) Patient has a pre-existing gastrointestinal medical condition; OR

Note: Examples of pre-existing gastrointestinal medical conditions include esophageal lesions, esophageal ulcers, or abnormalities of the esophagus that delay esophageal emptying (stricture, achalasia).

- iv. Patient meets ONE of the following (a or b):

- a) Patient meets BOTH of the following [(1) and (2)]:

- (1) According to the prescriber, the patient has severe renal impairment or chronic kidney disease; AND

Note: An example of severe renal impairment is a creatinine clearance < 35 mL/minute.

- (2) Patient has been evaluated for the presence of chronic kidney disease mineral and bone disorder to reduce the risk of Prolia-induced hypocalcemia; OR

- b) Patient has had an osteoporotic fracture or a fragility fracture.

Other Uses with Supportive Evidence

21. Treatment of Bone Loss in Patients with Prostate Cancer Receiving Androgen Deprivation Therapy. Approve for 1 year if the patient is receiving androgen deprivation therapy.

Note: Examples of androgen deprivation therapy are Lupron Depot (leuprolide depot suspension injection), Eligard (leuprolide acetate suspension injectable), Trelstar (triptorelin pamoate suspension injection), Zoladex (goserelin implant), and Orgovyx (relugolix tablets).

22. Increase Bone Mineral Density in Patients with Breast Cancer. Approve for 1 year if the patient meets ONE of the following (i or ii):

- i. Patient meets both of the following (a and b):

- a) Patient is postmenopausal; AND

- b) Patient is receiving aromatase inhibitor therapy; OR

Note: Examples of aromatase inhibitor therapy are anastrozole, letrozole, or exemestane.

- ii. Patient meets both of the following (a and b):

- a) Patient is premenopausal; AND

- b) Patient is receiving estrogen deprivation therapy.

Note: Examples of estrogen deprivation therapy are leuprolide acetate, Lupron Depot (leuprolide acetate intramuscular injection), Trelstar (triptorelin pamoate intramuscular injection), Zoladex (goserelin acetate subcutaneous injection), anastrozole, letrozole, and exemestane.

* Refer to the Policy Statement.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Prolia is not recommended in the following situations:

10/23/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

47. Concurrent Use with Other Medications for Osteoporosis.

Note: Examples of medications for osteoporosis that Prolia should not be given with include teriparatide subcutaneous injection (Forteo), Tymlos (abaloparatide subcutaneous injection), oral bisphosphonates (e.g., alendronate, risedronate, ibandronate), intravenous bisphosphonates (zoledronic acid intravenous infusion [Reclast], ibandronate intravenous infusion), calcitonin nasal spray (Miacalcin/Fortical), and Evenity (romosozumab-aqqg subcutaneous injection). Prolia is not indicated for use as combination therapy.¹ However, this does NOT exclude use of calcium and/or vitamin D supplements in combination with Prolia.

48. Giant Cell Tumor of Bone. Studies with denosumab in giant cell tumor of the bone used dosing for Xgeva, which is indicated for the treatment of adults and skeletally mature adolescents with giant cell tumor of bone that is unresectable or where surgical resection is likely to result in severe morbidity.²

49. Osteoporosis Prevention. Prolia is not indicated for the prevention of osteoporosis.¹

50. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

- POLICY:** Bone Modifiers – Teriparatide Products Prior Authorization Policy
- Forteo® (teriparatide subcutaneous injection – Eli Lilly, generic)
 - Teriparatide subcutaneous injection – Alvogen
 - Teriparatide subcutaneous injection – Almaject

REVIEW DATE: 10/23/2024; selected revision 10/30/2024

OVERVIEW

Teriparatide products, which are parathyroid hormone (PTH 1-34) analogs, are indicated for the following uses:¹⁻⁵

- **Glucocorticoid-induced osteoporosis (treatment)**, in men and women at high risk for fracture associated with sustained systemic glucocorticoid therapy (daily dosage equivalent to 5 mg or greater of prednisone).
- **Osteoporosis, treatment of postmenopausal women** at high risk for fracture.
- **Osteoporosis, to increase bone mass in men with primary or hypogonadal osteoporosis** at high risk for fracture.

In general, for all indications, patients at high risk for fracture are defined as those with a history of osteoporotic fractures, have multiple risk factors for fracture, or have failed or are intolerant to other osteoporosis therapy.¹⁻⁵

Teriparatide has been used for patients with hypoparathyroidism.⁶⁻¹³ Natpara® (parathyroid hormone subcutaneous injection) is indicated as an adjunct to calcium and vitamin D to control hypocalcemia in patients with hypoparathyroidism.¹⁴ However, there is a recall of Natpara and teriparatide is one of two main alternatives recommended in a joint guidance statement from the American Society for Bone and Mineral Research and Endocrine Society for patients with hypoparathyroidism transitioning from Natpara.¹⁵ It is notable that if teriparatide therapy is used in this clinical scenario, twice daily or even three times daily injections are usually needed.

Guidelines

Teriparatide is addressed in various clinical guidelines.¹⁶⁻¹⁹

- **Glucocorticoid-Induced Osteoporosis:** The American College of Rheumatology has guidelines for the prevention and treatment of glucocorticoid-induced osteoporosis (2022).¹⁶ In various clinical scenarios, teriparatide is recommended after trial of other agents (e.g., oral bisphosphonates, intravenous bisphosphonates).
- **Postmenopausal Osteoporosis:** Teriparatide products are mentioned in guidelines for postmenopausal osteoporosis by the Endocrine Society (2019)¹⁷ and the American Association of Clinical Endocrinologists and the American College of Endocrinology (2020)¹⁸. Teriparatide is one of several agents cited as an alternative for patients at very high risk for fractures or among those who cannot tolerate oral therapy. The Bone Health and Osteoporosis Foundation clinician guide for the prevention and treatment of osteoporosis (2022) cite robust reductions in vertebral and non-vertebral fractures with teriparatide.¹⁹

Safety

An increased incidence of osteosarcoma was noted in male and female rats who received teriparatide.¹ Osteosarcoma has been reported in patients treated with teriparatide in the post-marketing setting, however, an increased risk of osteosarcoma has not been observed in observational studies involving humans. There are limited data evaluating the risk of osteosarcoma beyond 2 years of teriparatide use. Avoid use of teriparatide in patients with a baseline risk of osteosarcoma. Use of teriparatide for more than 2 years during a patient's lifetime should only be considered if a patient remains at or has returned to having a high risk for fracture.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of teriparatide products. All approvals are provided for the duration noted below. For the indication of hypoparathyroidism, because of the specialized skills required for evaluation and diagnosis of patients treated with teriparatide as well as monitoring for adverse events and long-term efficacy, approval requires teriparatide to be prescribed by or in consultation with a physician who specializes in the condition being treated. In the approval indication, as appropriate, an asterisk (*) is noted next to the specified gender. In this context, the specified gender is defined as follows: men are defined as individuals with the biological traits of a man, regardless of the individual's gender identity or gender expression.

Automation: Smart Coverage Review uses patient claim history to answer Prior Authorization questions regarding medication history of Boniva® (ibandronate intravenous injection) or Reclast® (zoledronic acid intravenous infusion). A 2-year look back period will be used to check claim history and automate for use of either agent (Boniva intravenous or Reclast). If not in claims, medication can be obtained through Prior Authorization criteria. For all reviews, other Prior Authorization criteria listed below will also be applied.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of teriparatide products is recommended in those who meet one of the following criteria:

FDA-Approved Indications

1. Glucocorticoid-Induced Osteoporosis – Treatment. Approve for the duration noted below if the patient meets ALL of the following (A, B, and C):

C) Patient is either initiating or continuing systemic glucocorticoids; AND

Note: An example of a systemic glucocorticoid is prednisone.

D) Patient meets ONE of the following (i, ii, iii, or iv):

v. Patient has tried zoledronic acid intravenous infusion (Reclast); OR

vi. Patient has tried at least one oral bisphosphonate or oral bisphosphonate-containing product and meets ONE of the following (a or b):

Note: Examples of oral bisphosphonate products include Fosamax (alendronate tablets and oral solution), Fosamax Plus D (alendronate/cholecalciferol tablets), Actonel (risedronate tablets), Atelvia (risedronate delayed-release tablets), and Boniva (ibandronate tablets).

c) According to the prescriber, patient has experienced inadequate efficacy to oral bisphosphonate therapy after a trial duration of 12 months; OR

Note: Examples of inadequate efficacy are ongoing and significant loss of bone mineral density (BMD), lack of a BMD increase, and/or an osteoporotic fracture or a fragility fracture.

d) Patient has experienced significant intolerance to an oral bisphosphonate; OR

Note: Examples of significant intolerance include severe gastrointestinal-related adverse events and/or severe musculoskeletal related-adverse events.

vii. Patient cannot take an oral bisphosphonate due to ONE of the following (a, b, or c):

- d)** Patient cannot swallow or has difficulty swallowing; OR
- e)** Patient cannot remain in an upright position post oral bisphosphonate administration; OR
- f)** Patient has a preexisting gastrointestinal medical condition; OR

Note: Examples of preexisting gastrointestinal medical conditions include esophageal lesions, esophageal ulcers, or abnormalities of the esophagus that delay esophageal emptying (stricture, achalasia).

viii. Patient meets ONE of the following (a or b):

- a)** According to the prescriber, the patient has severe renal impairment or chronic kidney disease; OR

Note: An example of severe renal impairment is a creatinine clearance < 35 mL/minute.

- b)** Patient has had an osteoporotic fracture or a fragility fracture; AND

E) Patient meets ONE of the following (i or ii):

- i.** According to the prescriber, if the patient is at high risk for fracture, approve for ONE of the following (a or b):

Note: Examples of high risk for fracture include a previous osteoporotic fracture or fragility fracture, receipt of medications that increase the risk of osteoporosis, advanced age, and very low bone mineral density.

- a)** If patient is initiating therapy or has received a teriparatide product for < 1 year, approve for up to 2 years; OR

Note: For example, a patient who has already received 3 months of treatment with teriparatide should be approved for a duration of 21 months. This allows for completion of 2 years of therapy. Use of a teriparatide product beyond 2 years is evaluated annually for continued high risk of fracture.

- b)** If patient has already received ≥ 1 year of therapy with a teriparatide product, approve for 1 year.

Note: Use of a teriparatide product beyond 2 years is evaluated annually for continued high risk of fracture.

- ii.** According to the prescriber, if the patient is not at high risk for fracture, approve for the duration necessary to complete a maximum of 2 years of therapy (total) during a patient's lifetime.

Note: For example, a patient who has already received 3 months of treatment with teriparatide should be approved for a duration of 21 months. This allows for completion of a maximum of 2 years of therapy.

2. Osteoporosis Treatment for a Postmenopausal Patient. Approve for the duration noted below if the patient meets ALL of the following (A, B, and C):

A) Patient meets ONE of the following (i, ii, or iii):

- i.** Patient has had a T-score (current or at any time in the past) at or below -2.5 at the lumbar spine, femoral neck, total hip, and/or 33% (one-third) radius (wrist); OR

- ii.** Patient has had an osteoporotic fracture or a fragility fracture; OR

- iii.** Patient meets BOTH of the following (a and b):

- a)** Patient has low bone mass; AND

Note: An example of low bone mass includes a T-score (current or at any time in the past) between -1.0 and -2.5 at the lumbar spine, femoral neck, total hip and/or 33% (one-third) radius (wrist).

- b)** According to the prescriber, patient is at high risk for fracture; AND

B) Patient meets ONE of the following (i, ii, iii, or iv):

- i. Patient has tried ibandronate intravenous injection (Boniva) or zoledronic acid intravenous infusion (Reclast); OR
 - ii. Patient has tried at least one oral bisphosphonate or oral bisphosphonate-containing product and meets ONE of the following (a or b):
Note: Examples of oral bisphosphonate products include Fosamax (alendronate tablets and oral solution), Fosamax Plus D (alendronate/cholecalciferol tablets), Actonel (risedronate tablets), Atelvia (risedronate delayed-release tablets), and Boniva (ibandronate tablets).
 - a) According to the prescriber, patient has experienced inadequate efficacy to oral bisphosphonate therapy after a trial duration of 12 months; OR
Note: Examples of inadequate efficacy are ongoing and significant loss of bone mineral density (BMD), lack of a BMD increase, and/or an osteoporotic fracture or a fragility fracture.
 - b) Patient has experienced significant intolerance to an oral bisphosphonate; OR
Note: Examples of significant intolerance include severe gastrointestinal-related adverse events and/or severe musculoskeletal-related adverse events.
 - iii. Patient cannot take an oral bisphosphonate due to ONE of the following (a, b, or c):
 - a) Patient cannot swallow or has difficulty swallowing; OR
 - b) Patient cannot remain in an upright position post oral bisphosphonate administration; OR
 - c) Patient has a preexisting gastrointestinal medical condition; OR
Note: Examples of preexisting gastrointestinal medical conditions include esophageal lesions, esophageal ulcers, or abnormalities of the esophagus that delay esophageal emptying (stricture, achalasia).
 - iv. Patient meets ONE of the following (a or b):
 - a) According to the prescriber, the patient has severe renal impairment or chronic kidney disease; OR
Note: An example of severe renal impairment is a creatinine clearance < 35 mL/minute.
 - b) Patient has had an osteoporotic fracture or a fragility fracture; AND
- C) Patient meets ONE of the following (i or ii):
- i. According to the prescriber if the patient is at high risk for fracture, approve for ONE of the following (a or b):
Note: Examples of high risk for fracture include a previous osteoporotic fracture or fragility fracture, receipt of medications that increase the risk of osteoporosis, advanced age, and very low bone mineral density.
 - a) If patient is initiating therapy or has received a teriparatide product for < 1 year, approve for up to 2 years; OR
Note: For example, a patient who has already received 3 months of treatment with teriparatide should be approved for a duration of 21 months. This allows for completion of 2 years of therapy. Use of a teriparatide product beyond 2 years is evaluated annually for continued high risk of fracture.
 - b) If patient has already received ≥ 1 year of therapy with a teriparatide product, approve for 1 year.
Note: Use of a teriparatide product beyond 2 years is evaluated annually for continued high risk of fracture.
 - ii. According to the prescriber if the patient is not at high risk for fracture, approve for the duration necessary to complete a maximum of 2 years of therapy (total) during a patient's lifetime.
Note: For example, a patient who has already received 3 months of treatment with teriparatide should be approved for a duration of 21 months. This allows for completion of a maximum of 2 years of therapy.

3. Osteoporosis Treatment (to Increase Bone Mass) for Men* with Primary or Hypogonadal Osteoporosis. Approve for the duration noted below if the patient meets ALL of the following (A, B, and C):

A) Patient meets ONE of the following (i, ii, or iii):

- i.** Patient has had a T-score (current or at any time in the past) at or below -2.5 at the lumbar spine, femoral neck, total hip and/or 33% (one-third) radius (wrist); OR
- ii.** Patient has had an osteoporotic fracture or a fragility fracture; OR
- iii.** Patient meets BOTH of the following (a and b):
 - a)** Patient has low bone mass; AND
Note: An example of low bone mass includes a T-score (current or at any time in the past) between -1.0 and -2.5 at the lumbar spine, femoral neck, total hip and/or 33% (one-third) radius (wrist).
 - b)** According to the prescriber, patient is at high risk for fracture; AND

B) Patient meets ONE of the following (i, ii, iii, or iv):

- i.** Patient has tried zoledronic acid intravenous infusion (Reclast); OR
- ii.** Patient has tried at least one oral bisphosphonate or oral bisphosphonate-containing product and meets one of the following (a or b):
Note: Examples of oral bisphosphonate products include Fosamax (alendronate tablets and oral solution), Fosamax Plus D (alendronate/cholecalciferol tablets), Actonel (risedronate tablets), Atelvia (risedronate delayed-release tablets), and Boniva (ibandronate tablets).
 - a)** According to the prescriber, patient has experienced inadequate efficacy to oral bisphosphonate therapy after a trial duration of 12 months; OR
Note: Examples of inadequate efficacy are ongoing and significant loss of bone mineral density (BMD), lack of a BMD increase, and/or an osteoporotic fracture or a fragility fracture.
 - b)** Patient has experienced significant intolerance to an oral bisphosphonate; OR
Note: Examples of significant intolerance include severe gastrointestinal-related adverse events and/or severe musculoskeletal-related adverse events.
- iii.** Patient cannot take an oral bisphosphonate due to ONE of the following (a, b, or c):
 - a)** Patient cannot swallow or has difficulty swallowing; OR
 - b)** Patient cannot remain in an upright position post oral bisphosphonate administration; OR
 - c)** Patient has a preexisting gastrointestinal medical condition; OR
Note: Examples of preexisting gastrointestinal medical conditions include esophageal lesions, esophageal ulcers, or abnormalities of the esophagus that delay esophageal emptying (e.g., stricture, achalasia).
- iv.** Patient meets ONE of the following (a or b):
 - a)** According to the prescriber, the patient has severe renal impairment or chronic kidney disease; OR
Note: An example of severe renal impairment is a creatinine clearance < 35 mL/minute.
 - b)** Patient has had an osteoporotic fracture or a fragility fracture; AND

C) Patient meets ONE of the following (i or ii):

- i.** According to the prescriber if the patient is at high risk for fracture, approve for ONE of the following (a or b):
Note: Examples of high risk for fracture include a previous osteoporotic fracture or fragility fracture, receipt of medications that increase the risk of osteoporosis, advanced age, and very low bone mineral density.
- a)** If patient is initiating therapy or has received a teriparatide product for < 1 year, approve for up to 2 years; OR
Note: For example, a patient who has already received 3 months of treatment with teriparatide should be approved for a duration of 21 months. This allows for completion

of 2 years of therapy. Use of a teriparatide product beyond 2 years is evaluated annually for continued high risk of fracture.

- b) If patient has already received ≥ 1 year of therapy with a teriparatide product, approve for 1 year.

Note: Use of a teriparatide product beyond 2 years is evaluated annually for continued high risk of fracture.

- ii. According to the prescriber if the patient is not at high risk for fracture, approve for the duration necessary to complete a maximum of 2 years of therapy (total) during a patient's lifetime.

Note: For example, a patient who has already received 3 months of treatment with teriparatide should be approved for a duration of 21 months. This allows for completion of a maximum of 2 years of therapy.

* Refer to the Policy Statement.

Other Uses with Supportive Evidence

4. **Chronic Hypoparathyroidism.** Approve for 1 year if the patient meets BOTH of the following (A and B):

1. Patient meets ONE of the following (i or ii):

i. Patient has tried Natpara (parathyroid hormone subcutaneous injection); OR

ii. Patient has tried Yorvipath (palopegteriparatide subcutaneous injection); AND

Note: Approval for this use is a unique circumstance and the other criterion regarding the other indications do not apply.

2. Medication is prescribed by or in consultation with an endocrinologist or a nephrologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of teriparatide is not recommended in the following situations:

51. Concurrent Use with Other Medications for Osteoporosis.

Note: Examples of medications for osteoporosis that teriparatide should not be given with include Prolia (denosumab subcutaneous injection), oral bisphosphonates (e.g., alendronate, risedronate, ibandronate), intravenous bisphosphonates (zoledronic acid intravenous infusion [Reclast], intravenous ibandronate), calcitonin nasal spray (Miacalcin/Fortical), Tymlos (abaloparatide subcutaneous injection), and Evenity (romosozumab-aqqg subcutaneous injection). However, this does NOT exclude use of calcium and/or vitamin D supplements in combination with teriparatide.

52. **Osteoporosis Prevention.** Teriparatide products have not been studied in this patient population. The benefits and risks of building bone with teriparatide products in a condition in which substantial bone loss has not occurred have not been investigated.¹

53. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Bone Modifiers – Tymlos Prior Authorization Policy

- Tymlos® (abaloparatide subcutaneous injection – Radius)

REVIEW DATE: 10/23/2024

OVERVIEW

Tymlos, a human parathyroid hormone related peptide analog, is indicated for the following uses:¹

- **Osteoporosis, treatment of postmenopausal women**, at high risk for fracture.
- **Osteoporosis, treatment to increase bone density in men**, at high risk for fracture.

Patients at high risk for fracture are defined as those with a history of osteoporotic fracture, have multiple risk factors for fracture, or have failed or are intolerant to other osteoporosis therapy.

Guidelines

Guidelines for osteoporosis in postmenopausal women from the Endocrine Society (2019)² as well as from the American Association of Clinical Endocrinologists and the American College of Endocrinology (2020)³ discuss Tymlos. In general, Tymlos is one of several alternatives recommended in patients who are at high risk of fracture or in those unable to utilize oral bisphosphonate therapy. The Bone Health and Osteoporosis clinician guide to prevent and treat osteoporosis (2022) cites robust reductions in vertebral and non-vertebral fractures with Tymlos therapy in postmenopausal women with osteoporosis.⁴

Safety

The prescribing information for Tymlos states that the safety and efficacy of Tymlos have not been evaluated beyond 2 years of therapy. Use of the medication for more than 2 year during a patient's lifetime is not recommended. There are limited data evaluating the risk of osteosarcoma beyond 2 years of Tymlos and/or use of a parathyroid hormone analog. Avoid use of Tymlos in patients who are at increased baseline risk of osteosarcoma (e.g., open epiphyses [pediatric and young adult patients], those with metabolic bone disease, patients with bone metastases or a history of skeletal malignancies).

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Tymlos. All approvals are provided for the duration noted below. In the approval indication, as appropriate, an asterisk (*) is noted next to the specified gender. In this context, the specified gender is defined as follows: men are defined as individuals with the biological traits of a man, regardless of the individual's gender identity or gender expression.

Automation: Smart Coverage Review uses patient claim history to answer Prior Authorization questions regarding medication history of Boniva® (ibandronate intravenous injection) or Reclast® (zoledronic acid intravenous infusion). A 2-year look back period will be used to check claim history and automate for use of either agent (Boniva intravenous injection or Reclast). If not in claims, medication can be obtained through Prior Authorization criteria. For all reviews, other Prior Authorization criteria listed below will also be applied.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Tymlos is recommended in those who meet one of the following criteria:

FDA-Approved Indications

- 1. Osteoporosis Treatment for a Postmenopausal Patient.** Approve for up to 2 years (total) during a patient's lifetime if the patient meets BOTH of the following (A and B):

Note: For example, a patient who has already received 3 months of treatment with Tymlos should be approved for a duration of 21 months. This allows for completion of a maximum of 2 years of therapy during the patient's lifetime.

- D)** Patient meets ONE of the following (i, ii, or iii):

- iv.** Patient has had a T-score (current or at any time in the past) at or below -2.5 at the lumbar spine, femoral neck, total hip and/or 33% (one-third) radius (wrist); OR
- v.** Patient has had an osteoporotic fracture or a fragility fracture; OR
- vi.** The patient meets BOTH of the following (a and b):

- a)** Patient has low bone mass; AND

Note: An example of low bone mass includes a T-score (current or at any time in the past) between -1.0 and -2.5 at the lumbar spine, femoral neck, total hip, and/or 33% (one-third) radius (wrist).

- b)** According to the prescriber, patient is at high risk for fracture; AND

- E)** Patient meets ONE of the following (i, ii, iii, or iv):

- v.** Patient has tried ibandronate intravenous injection (Boniva) or zoledronic acid intravenous infusion (Reclast); OR

- vi.** Patient has tried at least one oral bisphosphonate or oral bisphosphonate-containing product and meets ONE of the following (a or b):

Note: Examples of oral bisphosphonate products include Fosamax (alendronate tablets and oral solution), Fosamax Plus D (alendronate/cholecalciferol tablets), Actonel (risedronate tablets), Atelvia (risedronate delayed-release tablets), and Boniva (ibandronate tablets).

- c)** According to the prescriber, patient has experienced inadequate efficacy to oral bisphosphonate therapy after a trial duration of 12 months; OR

Note: Examples of inadequate efficacy are ongoing and significant loss of bone mineral density (BMD), lack of a BMD increase, and/or an osteoporotic fracture or a fragility fracture.

- d)** Patient has experienced significant intolerance to an oral bisphosphonate; OR

Note: Examples of significant intolerance include severe gastrointestinal related adverse events and/or severe musculoskeletal related adverse events.

- vii.** Patient cannot take an oral bisphosphonate due to ONE of the following (a, b, or c):

- a)** Patient cannot swallow or has difficulty swallowing; OR

- b)** Patient cannot remain in an upright position post oral bisphosphonate administration; OR

- c)** Patient has a pre-existing gastrointestinal medical condition; OR

Note: Examples of pre-existing gastrointestinal medical conditions include esophageal lesions, esophageal ulcers, or abnormalities of the esophagus that delay esophageal emptying (stricture, achalasia).

- viii.** Patient meets ONE of the following (a or b):

- c)** According to the prescriber, the patient has severe renal impairment or chronic kidney disease; OR

Note: An example of severe renal impairment is a creatinine clearance < 35 mL/minute.

- d)** Patient has had an osteoporotic fracture or a fragility fracture.

2. Osteoporosis Treatment for Men*. Approve for up to 2 years (total) during a patient's lifetime if the patient meets BOTH of the following (A and B):

Note: For example, a patient who has already received 3 months of treatment with Tymlos should be approved for a duration of 21 months. This allows for completion of a maximum of 2 years of therapy during the patient's lifetime.

A) Patient meets ONE of the following (i, ii, or iii):

- i.** Patient has had a T-score (current or at any time in the past) at or below -2.5 at the lumbar spine, femoral neck, total hip and/or 33% (one-third) radius (wrist); OR
- ii.** Patient has had an osteoporotic fracture or a fragility fracture; OR
- iii.** The patient meets BOTH of the following (a and b):

a) Patient has low bone mass; AND

Note: An example of low bone mass includes a T-score (current or at any time in the past) between -1.0 and -2.5 at the lumbar spine, femoral neck, total hip, and/or 33% (one-third) radius (wrist).

b) According to the prescriber, patient is at high risk for fracture; AND

B) Patient meets ONE of the following (i, ii, iii, or iv):

- i.** Patient has tried zoledronic acid intravenous infusion (Reclast); OR
- ii.** Patient has tried at least one oral bisphosphonate or oral bisphosphonate-containing product and meets ONE of the following (a or b):

Note: Examples of oral bisphosphonate products include Fosamax (alendronate tablets and oral solution), Fosamax Plus D (alendronate/cholecalciferol tablets), Actonel (risedronate tablets), Atelvia (risedronate delayed-release tablets), and Boniva (ibandronate tablets).

a) According to the prescriber, patient has experienced inadequate efficacy to oral bisphosphonate therapy after a trial duration of 12 months; OR

Note: Examples of an inadequate efficacy are ongoing and significant loss of bone mineral density (BMD), lack of a BMD increase, and/or an osteoporotic fracture or a fragility fracture.

b) Patient has experienced significant intolerance to an oral bisphosphonate; OR

Note: Examples of significant intolerance include severe gastrointestinal related adverse events and/or severe musculoskeletal related adverse events.

iii. Patient cannot take an oral bisphosphonate due to ONE of the following (a, b, or c):

a) Patient cannot swallow or has difficulty swallowing; OR

b) Patient cannot remain in an upright position post oral bisphosphonate administration; OR

c) Patient has a pre-existing gastrointestinal medical condition; OR

Note: Examples of pre-existing gastrointestinal medical conditions include esophageal lesions, esophageal ulcers, or abnormalities of the esophagus that delay esophageal emptying (stricture, achalasia).

iv. Patient meets ONE of the following (a or b):

a) According to the prescriber, the patient has severe renal impairment or chronic kidney disease; OR

Note: An example of severe renal impairment is a creatinine clearance < 35 mL/minute.

b) Patient has had an osteoporotic fracture or a fragility fracture.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Tymlos is not recommended in the following situations:

54. Concurrent Use with Other Medications for Osteoporosis.

Note: Examples of medications for osteoporosis that Tymlos should not be given with include Prolia (denosumab subcutaneous injection), oral bisphosphonates (alendronate, risedronate, ibandronate),

intravenous bisphosphonates (zoledronic acid intravenous infusion [Reclast], ibandronate intravenous injection), calcitonin nasal spray (Miacalcin/Fortical), teriparatide subcutaneous injection (Forteo), and Evenity (romosozumab-aqqg subcutaneous injection). However, this does NOT exclude use of calcium and/or vitamin D supplements in combination with Tymlos.

55. **Osteoporosis Prevention.** Tymlos has not been studied in this patient population. The benefits and risks of building bone with Tymlos in a condition in which substantial bone loss has not occurred have not been investigated.¹
56. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Bone Modifiers – Xgeva Prior Authorization Policy

- Xgeva® (denosumab subcutaneous injection – Amgen)

REVIEW DATE: 03/13/2024

OVERVIEW

Xgeva, a receptor activator of nuclear factor kappa-B ligand inhibitor, is indicated for the following uses:¹

- **Giant cell tumor of bone**, treatment of adults and skeletally mature adolescents with disease that is unresectable or where surgical resection is likely to result in severe morbidity.
- **Hypercalcemia of malignancy**, treatment of, that is refractory to bisphosphonate therapy.
- **Skeletal-related events**, prevention of, in patients with multiple myeloma and in those with bone metastases from solid tumors.

Another injectable formulation of denosumab is available, Prolia® (subcutaneous injection), but it is not included in this policy.²

Guidelines

Several guidelines address Xgeva.

- **Cancer:** Various guidelines from the National Comprehensive Cancer Network (e.g., breast cancer, prostate cancer, lung cancer, multiple myeloma) recommend Xgeva for the prevention of skeletal related adverse events.³⁻⁶
- **Hypercalcemia of Malignancy:** Guidelines from the Endocrine Society for the treatment of hypercalcemia of malignancy in adults (2023) have several recommendations.⁷ In adults with hypercalcemia of malignancy, treatment with Xgeva over an intravenous bisphosphonate is recommended.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Xgeva. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Xgeva as well as the monitoring required for adverse events and long-term efficacy, approval requires Xgeva to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Xgeva is recommended in those who meet one of the following criteria:

FDA-Approved Indications

1. **Bone Metastases from Solid Tumors – Prevention of Skeletal-Related Events.** Approve for 1 year if the patient meets ALL of the following (A, B, C, and D):

Note: Some examples of cancer in this clinical scenario include breast cancer, prostate cancer, and non-small cell lung cancer.

03/13/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- A) Patient is ≥ 18 years of age; AND
 - B) Patient has bone metastases; AND
 - C) Patient with prostate cancer must have castration-resistant prostate cancer; AND
Note: This includes patients who have progressed after treatment with hormonal therapy or after surgical castration (e.g., bilateral orchiectomy). Examples of hormonal therapies for prostate cancer include Lupron Depot (leuprolide for depot suspension), Eligard (leuprolide acetate for injectable suspension), Trelstar (triptorelin pamoate for injectable suspension), or Zoladex (goserelin implant).
 - D) The medication is prescribed by or in consultation with a hematologist or an oncologist.
2. **Giant Cell Tumor of Bone.** Approve for 1 year.
3. **Hypercalcemia of Malignancy.** Approve for 2 months if the patient meets BOTH of the following (A and B):
- A) Patient has a current malignancy; AND
 - B) Patient has an albumin-corrected calcium (cCa) ≥ 11.5 mg/dL.
4. **Multiple Myeloma – Prevention of Skeletal-Related Events.** Approve for 1 year if the patient meets BOTH of the following (A and B):
- A) Patient is ≥ 18 years of age; AND
 - B) Medication is prescribed by or in consultation with a hematologist or an oncologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Xgeva is not recommended in the following situations:

- 27. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Bone Modifiers – Zoledronic Acid (Reclast) Prior Authorization Policy

- Reclast® (zoledronic acid intravenous infusion – Novartis, generic)

REVIEW DATE: 03/13/2024

OVERVIEW

Zoledronic acid (Reclast), a bisphosphonate given intravenously, is indicated for the following uses:¹

- **Glucocorticoid-induced osteoporosis**, for treatment and prevention in men and women who are either initiating or continuing systemic glucocorticoids (e.g., prednisone 7.5 mg or greater) and who are anticipated to remain on glucocorticoids for at least 12 months.
- **Osteoporosis, prevention in postmenopausal women.**
- **Osteoporosis, treatment in men** to increase bone mass.
- **Osteoporosis, treatment in postmenopausal women.**
- **Paget's disease of bone**, treatment in men and women.

Another zoledronic acid injection product, Zometa®, is indicated for hypercalcemia of malignancy; and for multiple myeloma and bone metastases from solid tumors.² Although not indicated, zoledronic acid injection (Reclast) has been used in patients, mainly children, with osteogenesis imperfecta and benefits were noted, such as increases in bone mineral density.^{1,3-9}

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of zoledronic acid injection (Reclast). All approvals are provided for the duration noted below. Regarding the approval duration of one dose, the approval is for 30 days, which is an adequate duration for the patient to receive one dose. In the approval indication for zoledronic acid injection (Reclast), as appropriate, an asterisk (*) is noted next to the specified gender. In this context, the specified gender is defined as follows: men are defined as individuals with the biological traits of a man, regardless of the individual's gender identity or gender expression.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of zoledronic acid injection (Reclast) is recommended in those who meet one of the following criteria:

FDA-Approved Indications

1. **Glucocorticoid-Induced Osteoporosis – Prevention and Treatment.** Approve for 1 year if the patient meets BOTH of the following (A and B):
 - A) Patient is either initiating or continuing systemic glucocorticoids; AND
Note: An example of a systemic glucocorticoid is prednisone.
 - B) Patient meets ONE of the following (i, ii, iii, or iv):
 - i. Patient has tried zoledronic acid intravenous infusion (Reclast); OR
 - ii. Patient has tried at least one oral bisphosphonate or oral bisphosphonate-containing product and meets ONE of the following (a or b):

03/13/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Note: Examples of oral bisphosphonate products include Fosamax (alendronate tablets and oral solution), Fosamax Plus D (alendronate/cholecalciferol tablets), Actonel (risedronate tablets), Atelvia (risedronate delayed-release tablets), and Boniva (ibandronate tablets).

- a) According to the prescriber, patient has experienced inadequate efficacy to oral bisphosphonate therapy after a trial duration of 12 months; OR

Note: Examples of inadequate efficacy are ongoing and significant loss of bone mineral density (BMD), lack of a BMD increase, and/or an osteoporotic fracture or a fragility fracture.

- b) Patient has experienced significant intolerance to an oral bisphosphonate; OR

Note: Examples of significant intolerance include severe gastrointestinal related adverse events, severe musculoskeletal related adverse events, and femoral fracture.

- iii. Patient cannot take an oral bisphosphonate due to ONE of the following (a, b, or c):

- a) Patient cannot swallow or has difficulty swallowing; OR

- b) Patient cannot remain in an upright position post-oral bisphosphonate administration; OR

- c) Patient has a pre-existing gastrointestinal medical condition in which intravenous bisphosphonate therapy may be warranted; OR

Note: Examples of pre-existing gastrointestinal medical conditions include esophageal lesions, esophageal ulcers, and abnormalities of the esophagus that delay esophageal emptying (stricture, achalasia).

- iv. Patient has had an osteoporotic fracture or a fragility fracture.

2. Osteoporosis – Prevention for a Postmenopausal Patient. Approve for 1 year if the patient meets ALL of the following (A, B, and C):

- A) Patient meets ONE of the following (i or ii):

- i. Patient has had a T-score (current or at any time in the past) between -1.0 and -2.5 at the lumbar spine, femoral neck, total hip, and/or 33% (one third) radius (wrist); OR

- ii. Patient has had an osteoporotic fracture or a fragility fracture; AND

- B) Patient meets ONE of the following (i, ii, iii, or iv):

- i. Patient has tried zoledronic acid intravenous infusion (Reclast); OR

- ii. Patient has tried at least one oral bisphosphonate or oral bisphosphonate-containing product and meets ONE of the following (a or b):

Note: Examples of oral bisphosphonate products include Fosamax (alendronate tablets and oral solution), Fosamax Plus D (alendronate/cholecalciferol tablets), Actonel (risedronate tablets), Atelvia (risedronate delayed-release tablets), and Boniva (ibandronate tablets).

- a) According to the prescriber, patient has experienced inadequate efficacy to oral bisphosphonate therapy after a trial duration of 12 months; OR

Note: Examples of inadequate efficacy are ongoing and significant loss of bone mineral density (BMD), lack of a BMD increase, and/or an osteoporotic fracture or a fragility fracture.

- b) Patient has experienced significant intolerance to an oral bisphosphonate; OR

Note: Examples of significant intolerance include severe gastrointestinal related adverse events, severe musculoskeletal related adverse events, and femoral fracture.

- iii. Patient cannot take an oral bisphosphonate due to ONE of the following (a, b, or c):

- a) Patient cannot swallow or has difficulty swallowing; OR

- b) Patient cannot remain in an upright position post oral bisphosphonate administration; OR

- c) Patient has a pre-existing gastrointestinal medical condition in which intravenous bisphosphonate therapy may be warranted; OR

Note: Examples of pre-existing gastrointestinal medical conditions include esophageal lesions, esophageal ulcers, and abnormalities of the esophagus that delay esophageal emptying (stricture, achalasia).

- iv. Patient has had an osteoporotic fracture or a fragility fracture; AND
 - C) If the patient has received Reclast previously, at least 24 months has elapsed since the last dose.
- 3. Osteoporosis – Treatment for a Man*.** Approve for 1 year if the patient meets BOTH of the following (A and B):
- A) Patient meets ONE of the following (i, ii, or iii):
 - i. Patient has had a T-score (current or at any time in the past) at or below -2.5 at the lumbar spine, femoral neck, total hip, and/or 33% (one third) radius (wrist); OR
 - ii. Patient has had an osteoporotic fracture or a fragility fracture; OR
 - iii. Patient meets BOTH of the following (a and b):
 - a) Patient has low bone mass; AND
Note: An example of low bone mass includes a T-score (current or at any time in the past) between -1.0 and -2.5 at the lumbar spine, femoral neck, total hip, and/or 33% (one-third) radius (wrist).
 - b) According to the prescriber, patient is at high risk for fracture; AND
 - B) Patient meets ONE of the following (i, ii, iii, or iv):
 - i. Patient has tried zoledronic acid intravenous infusion (Reclast); OR
 - ii. Patient has tried at least one oral bisphosphonate or oral bisphosphonate-containing product and meets ONE of the following (a or b):
Note: Examples of oral bisphosphonate products include Fosamax (alendronate tablets and oral solution), Fosamax Plus D (alendronate/cholecalciferol tablets), Actonel (risedronate tablets), Atelvia (risedronate delayed-release tablets), and Boniva (ibandronate tablets).
 - a) According to the prescriber, patient has experienced inadequate efficacy to oral bisphosphonate therapy after a trial duration of 12 months; OR
Note: Examples of inadequate efficacy are ongoing and significant loss of bone mineral density (BMD), lack of a BMD increase, and/or an osteoporotic fracture or a fragility fracture.
 - b) Patient has experienced significant intolerance to an oral bisphosphonate; OR
Note: Examples of significant intolerance include severe gastrointestinal related adverse events, severe musculoskeletal related adverse events, and femoral fracture.
 - iii. Patient cannot take an oral bisphosphonate due to ONE of the following (a, b, or c):
 - a) Patient cannot swallow or has difficulty swallowing; OR
 - b) Patient cannot remain in an upright position post oral bisphosphonate administration; OR
 - c) Patient has a pre-existing gastrointestinal medical condition in which intravenous bisphosphonate therapy may be warranted; OR
Note: Examples of pre-existing gastrointestinal medical conditions include esophageal lesions, esophageal ulcers, and abnormalities of the esophagus that delay esophageal emptying (stricture, achalasia).
 - iv. Patient has had an osteoporotic fracture or a fragility fracture.

* Refer to the Policy Statement.

- 4. Osteoporosis – Treatment for a Postmenopausal Patient.** Approve for 1 year if the patient meets BOTH of the following (A and B):
- A) Patient meets ONE of the following conditions (i, ii, or iii):
 - i. Patient has had a T-score (current or at any time in the past) at or below -2.5 at the lumbar spine, femoral neck, total hip, and/or 33% (one-third) radius (wrist); OR
 - ii. Patient has had an osteoporotic fracture or a fragility fracture; OR
 - iii. Patient meets BOTH of the following (a and b):
 - a) Patient has low bone mass; AND

Note: An example of low bone mass includes a T-score (current or at any time in the past) between -1.0 and -2.5 at the lumbar spine, femoral neck, total hip, and/or 33% (one-third) radius (wrist).

b) According to the prescriber, patient is at high risk for fracture; AND

B) Patient meets ONE of the following (i, ii, iii, or iv):

i. Patient has tried ibandronate intravenous infusion (Boniva IV) or zoledronic acid intravenous infusion (Reclast); OR

ii. Patient has tried at least one oral bisphosphonate or oral bisphosphonate-containing product and meets ONE of the following (a or b):

Note: Examples of oral bisphosphonate products include Fosamax (alendronate tablets and oral solution), Fosamax Plus D (alendronate/cholecalciferol tablets), Actonel (risedronate tablets), Atelvia (risedronate delayed-release tablets), and Boniva (ibandronate tablets).

a) According to the prescriber, patient has experienced inadequate efficacy to oral bisphosphonate therapy after a trial duration of 12 months; OR

Note: Examples of inadequate efficacy are ongoing and significant loss of bone mineral density (BMD), lack of a BMD increase, and/or an osteoporotic fracture or a fragility fracture.

b) Patient has experienced significant intolerance to an oral bisphosphonate; OR

Note: Examples of significant intolerance include severe gastrointestinal related adverse events, severe musculoskeletal related adverse events, and femoral fracture.

iii. Patient cannot take an oral bisphosphonate due to ONE of the following (a, b, or c):

a) Patient cannot swallow or has difficulty swallowing; OR

b) Patient cannot remain in an upright position post oral bisphosphonate administration; OR

c) Patient has a pre-existing gastrointestinal medical condition in which intravenous bisphosphonate therapy may be warranted; OR

Note: Examples of pre-existing gastrointestinal medical conditions include esophageal lesions, esophageal ulcers, and abnormalities of the esophagus that delay esophageal emptying (stricture, achalasia).

iv. Patient has had an osteoporotic fracture or a fragility fracture.

5. **Paget's Disease of Bone.** Approve for one dose if the patient meets ONE of the following (A, B, or C):

A) Patient has elevations in serum alkaline phosphatase of two times higher than the upper limit of the age-specific normal reference range; OR

B) Patient is symptomatic; OR

Note: Examples of symptoms include bone pain, hearing loss, and osteoarthritis.

C) Patient is at risk for complications from their disease.

Note: Examples of disease complications include immobilization, bone deformity, fractures, and nerve compression syndrome.

Other Uses with Supportive Evidence

6. **Osteogenesis Imperfecta.** Approve for 1 year.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of zoledronic acid injection (Reclast) is not recommended in the following situations:

1. Concurrent Use of Zoledronic Acid Intravenous Infusion (Reclast) with Other Medications for Osteoporosis.

Note: Examples of medications for osteoporosis that zoledronic acid intravenous infusion (Reclast) should not be given with include oral bisphosphonates (e.g., alendronate, risedronate, ibandronate), other intravenous bisphosphonates (e.g., intravenous ibandronate [Boniva]), Prolia (denosumab subcutaneous injection), Evenity (romosozumab-aqqg subcutaneous injection), Forteo (teriparatide subcutaneous injection, generic), Tymlos (abaloparatide subcutaneous injection), and calcitonin nasal spray. This only applies to the osteoporosis-related indications. However, this does NOT exclude use of calcium and/or vitamin D supplements in combination with zoledronic acid intravenous infusion (Reclast). This criterion applies only to osteoporosis-related indications.

2. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Bone Modifiers – Zoledronic Acid (Zometa) Prior Authorization Policy

- Zometa® (zoledronic acid intravenous infusion – generic only)

REVIEW DATE: 03/13/2024

OVERVIEW

Zoledronic acid intravenous infusion (Zometa), a bisphosphonate, is indicated for the treatment of the following:¹

- **Hypercalcemia of malignancy.**
- **Multiple myeloma and documented bone metastases from solid tumors**, in addition to standard antineoplastic therapy.

Prostate cancer should have progressed after treatment with at least one hormonal therapy.¹ Another formulation of zoledronic acid intravenous infusion (Reclast®) is available but is not included in this policy.²

Data are available with zoledronic acid intravenous infusion (Zometa) regarding off-label uses. One example is to prevent bone loss in patients with breast cancer receiving aromatase inhibitor therapy. Aromatase inhibitor therapy prevents peripheral production and suppresses estrogen levels and can lead to accelerated bone loss beyond what would naturally occur in women.^{3,4} This can place the patient at an increased risk for having a fracture. A review on the management of aromatase inhibitor-associated bone loss in postmenopausal women with breast cancer⁵ states that zoledronic acid intravenous infusion (Zometa) [4 mg every 6 months] is the preferred agent for prevention and treatment of aromatase inhibitor bone loss.⁴ Zoledronic acid intravenous infusion (Zometa) has been studied and shown benefits in postmenopausal women receiving adjuvant letrozole for breast cancer.^{5,6}

Zoledronic acid intravenous infusion (Zometa) has also been utilized to prevent bone loss in patients with prostate cancer who are receiving androgen deprivation therapy (ADT). ADT is associated with a variety of adverse events, including osteoporosis. The National Comprehensive Cancer Network (NCCN) clinical practice guidelines regarding prostate cancer (version 3.2024 – March 8, 2024)⁷ cite zoledronic acid as an option to increase bone density, a surrogate for fracture risk, during ADT for prostate cancer. Zoledronic acid intravenous infusion (Zometa) has led to bone mineral density increases in patients with prostate cancer who are receiving androgen deprivation therapy.^{8,9} A clinical practice guideline for osteoporosis in men from the Endocrine Society⁹ recommends pharmacological treatment for osteoporosis for men with prostate cancer receiving ADT who have a high risk of fracture.

Zoledronic acid intravenous infusion (Zometa) has utility in premenopausal patients with breast cancer who have developed ovarian failure. Chemotherapy-induced ovarian failure is an adverse effect associated with some adjuvant chemotherapy and can lead to rapid bone loss.^{10,11} Studies have demonstrated zoledronic acid intravenous infusion (Zometa) to be efficacious in preserving bone mineral density in premenopausal women with breast cancer who developed ovarian failure due to adjuvant chemotherapy.

The American Society of Clinical Oncology and the Cancer Care Ontario group updated guidelines for use of adjuvant bisphosphonates and other bone-modifying agents in breast cancer. The guideline recommend adjuvant bisphosphonate therapy in postmenopausal patients with primary breast cancer who are candidates to receive adjuvant systemic therapy.¹² NCCN guidelines for breast cancer (version 1.2024 – January 25,

03/13/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

2024) also recommend bisphosphonates as adjuvant therapy for postmenopausal women with breast cancer.¹³

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of zoledronic acid intravenous infusion (Zometa). All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with zoledronic acid intravenous infusion (Zometa) as well as the monitoring required for adverse events and long-term efficacy, approval requires zoledronic acid intravenous infusion (Zometa) to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of zoledronic acid intravenous infusion (Zometa) is recommended in those who meet one of the following criteria:

FDA-Approved Indications

22. Bone Metastases From Solid Tumors – Prevention of Skeletal-Related Events. Approve for 1 year if the patient meets ALL of the following (A, B, and C):

Note: Some examples of cancer in this clinical scenario include breast cancer, prostate cancer, non-small cell lung cancer, renal cell cancer, small cell lung cancer, colorectal cancer, bladder cancer, gastrointestinal cancer, genitourinary cancer, and head and neck cancer.

A) Patient has bone metastases; AND

B) Patient with prostate cancer must have castration-resistant prostate cancer; AND

Note: This includes patients who have progressed after treatment with hormonal therapy or after surgical castration (e.g., bilateral orchiectomy). Examples of hormonal therapies for prostate cancer include Lupron Depot (leuprolide for depot suspension), Eligard (leuprolide acetate for injectable suspension), Trelstar (triptorelin pamoate for injectable suspension), and Zoladex (goserelin implant).

C) The medication is prescribed by or in consultation with a hematologist or an oncologist.

23. Hypercalcemia of Malignancy. Approve for 1 month if the patient meets BOTH of the following (A and B):

A) Patient has a current malignancy; AND

B) Patient has an albumin-corrected calcium (cCa) ≥ 11.5 mg/dL.

24. Multiple Myeloma – Prevention of Skeletal-Related Events. Approve for 1 year if the agent is prescribed by or in consultation with a hematologist or an oncologist.

Other Uses with Supportive Evidence

25. Breast Cancer – Adjuvant Therapy. Approve for 1 year if the patient is postmenopausal.

26. Prevention of Bone Loss (To Increase Bone Mass) in a Patient with Breast Cancer Receiving Aromatase Inhibitor Therapy. Approve for 1 year if the patient meets BOTH of the following (A and B):

A) Patient has breast cancer that is not metastatic to bone; AND

B) Patient is receiving an aromatase inhibitor therapy.

Note: Examples of aromatase inhibitor agents include anastrozole, letrozole, and exemestane.

27. Prevention of Bone Loss (To Increase Bone Mass) in a Patient with Prostate Cancer Who are Receiving Androgen Deprivation Therapy (ADT). Approve for 1 year if the patient meets BOTH of the following (A and B):

A) Patient has prostate cancer that is not metastatic to bone; AND

B) Patient meets ONE of the following (i or ii):

i. Patient is currently receiving androgen deprivation therapy; OR

Note: Examples of androgen deprivation therapies include Lupron Depot (leuprolide for depot suspension), Eligard (leuprolide acetate for injectable suspension), Trelstar (triptorelin pamoate for injectable suspension), or Zoladex (goserelin implant).

ii. Patient has undergone bilateral orchiectomy.

28. Prevention of Bone Loss (to Increase Bone Mass) in a Premenopausal Patient with Breast Cancer Who Has Developed Ovarian Failure. Approve for 1 year if the patient meets ALL of the following (A, B, and C):

A) Patient is premenopausal; AND

B) Breast cancer is not metastatic to bone; AND

C) Patient received adjuvant chemotherapy that led to ovarian failure.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of zoledronic acid intravenous infusion (Zometa) is not recommended in the following situations:

28. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Botulinum Toxins – Botox Prior Authorization Policy

- Botox® (onabotulinumtoxinA injection – Allergan/AbbVie)

REVIEW DATE: 10/02/2024

OVERVIEW

Botox (onabotulinumtoxinA), an acetylcholine release inhibitor and neuromuscular-blocking agent, is indicated for the following uses:¹

- **Blepharospasm** associated with dystonia, including benign essential blepharospasm or seventh (VII) nerve disorders in patients ≥ 12 years of age.
- **Cervical dystonia**, to reduce the severity of abnormal head position and neck pain associated with cervical dystonia in adults.
- **Hyperhidrosis, severe primary axillary** which is inadequately managed with topical agents in adults.
- **Migraine headache prophylaxis (prevention)**, in adults with chronic migraine (≥ 15 days per month with headache lasting 4 hours a day or longer).
- **Neurogenic detrusor overactivity (NDO) in pediatric patients** ≥ 5 years of age who have had an inadequate response to or are intolerant of an anticholinergic medication.
- **Overactive bladder (OAB)** with symptoms of urge urinary incontinence, urgency, and frequency, in adults who have had an inadequate response to or are intolerant of an anticholinergic medication.
- **Spasticity** in patients ≥ 2 years of age.
- **Strabismus** in patients ≥ 12 years of age.
- **Urinary incontinence due to detrusor overactivity associated with a neurological condition** (e.g., spinal cord injury, multiple sclerosis) in adults who have had an inadequate response to or are intolerant of an anticholinergic medication.

In regard to the indication of migraine headache prophylaxis, an updated position statement for the prevention of migraines from the American Headache Society (2024) notes that specifically for prevention of chronic migraine with or without aura, Botox should be considered a first-line treatment recommendation without a requirement for prior failure of other classes of migraine preventative treatment.²

Other Uses with Supportive Evidence

Botulinum toxin type A has been used to treat a multitude of disorders characterized by abnormal muscle contraction and the benefit of these products has also been demonstrated in the treatment of gastrointestinal, genitourinary, ocular, and autonomic nervous system disorders.^{3,8}

Botulinum toxins have been studied in a variety of indications outside of FDA-approved uses.¹⁸⁻²⁰ Literature is available to support use of Botox in the following conditions:

- **Achalasia:** The American College of Gastroenterology (ACG) clinical guideline for the diagnosis and management of esophageal achalasia (2020) recommends the use of botulinum toxin (formulation not specified) as first-line therapy for patients with achalasia who are unfit for definitive therapies for the treatment of achalasia such as pneumatic dilation or surgical myotomy.⁴
- **Anal Fissures:** The ACG clinical guideline for the management of benign anorectal disorders (2021) suggests that botulinum toxin A injections (formulation not specified) may be attempted for patients with chronic anal fissures in whom calcium channel blockers fail or as an alternative option to calcium channel blockers (conditional recommendation; quality of evidence low).⁵

10/02/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- **Dystonia, Focal Upper Limb:** Historical guidelines for the treatment of movement disorders from the American Academy of Neurology (AAN) support use of botulinum toxins in focal limb dystonia of the upper extremity (focal hand dystonia, i.e. writer's cramp) [Level B recommendation].⁷ Botulinum toxin is considered the treatment of choice for most focal dystonias.⁶ An evidence-based review and assessment (2013) for the treatment of focal upper limb dystonia indicate Botox should be considered (Level B recommendation).²⁸
- **Essential Tremor:** According to the clinical practice parameter on essential tremor by the AAN (2011; reaffirmed 2022), propranolol and primidone are first-line therapy in the treatment of essential tremor.¹⁴ Second-line medication options include alprazolam, atenolol, sotalol, gabapentin (as monotherapy), and topiramate. Botulinum toxin A may also reduce tremor. The guidelines recommend that botulinum toxin A may be considered in medically refractory cases of limb, head, and voice tremor associated with essential tremor (Level C for limb, head, and voice tremor).
- **Hemifacial Spasm:** Per historical AAN guidelines for the treatment of movement disorders, botulinum toxin (formulation not specified) may be considered in hemifacial spasm (Level C recommendation).⁷ Data with Botox and Dysport® (abobotulinumtoxinA injection) are cited in the recommendations regarding hemifacial spasm. An evidenced-based review and assessment (2013) for the treatment of hemifacial spasm indicate Botox® (onabotulinumtoxinA injection) should be considered (Level B recommendation) and Dysport may be considered (Level C recommendation).²⁸
- **Hyperhidrosis, Gustatory:** Botox is recommended as a first-line option for gustatory sweating by the International Hyperhidrosis Society.¹⁵
- **Hyperhidrosis, Primary Palmar, Plantar, and Facial:** Guidelines from the International Hyperhidrosis Society support use of Botox in patients with focal palmar, plantar, and craniofacial hyperhidrosis who have failed to respond to topical antiperspirant therapy.¹⁵⁻¹⁷ The efficacy of Botox is well-established in the treatment of primary and focal palmar hyperhidrosis based on data from both randomized, double-blind, placebo-controlled studies and open-label studies.^{19,21}
- **Laryngeal Dystonia (Spasmodic Dysphonia):** Botulinum toxin A is the most widely accepted treatment for spasmodic dysphonia, a focal laryngeal dystonia, and is viewed as the treatment of choice by the American Academy of Otolaryngology-Head and Neck Surgery (2018).⁹ Per the guideline, clinicians should offer, or refer to a clinician who can offer, botulinum toxin injections for treatment of dysphonia caused by spasmodic dysphonia and other types of laryngeal dystonia. Historical AAN guidelines for the treatment of movement disorders note that botulinum toxin is probably effective and should be considered for adductor type laryngeal dystonia (spasmodic dysphonia) [Level B recommendation].⁷ An evidence-based review and assessment (2013) for the treatment of adductor laryngeal dystonia indicate Botox may be considered (Level C recommendation).²⁸
- **Oromandibular Dystonia:** Small clinical trials have shown botulinum toxin A to be effective in treating oromandibular dystonia.^{11,12} The American Academy of Oral Medicine clinical practice statement on oromandibular dystonia recommend the use of botulinum type A injections (Botox is mentioned).¹⁰ A five year trial with Dysport for the treatment of focal movement disorders including oromandibular dystonia showed effectiveness and no new safety concerns.¹³ An evidence-based review and assessment (2013) for the treatment of oromandibular dystonia indicate Botox and Dysport may be considered (level C recommendation).²⁸ Of note, Meige syndrome is a variant that describes the co-existence of blepharospasm and oromandibular dystonia.²⁷
- **Sialorrhea:** Botulinum toxin A has been studied in the treatment of sialorrhea associated with Parkinson's Disease, parkinsonian syndromes, cerebral palsy, head and neck carcinoma, neurodegenerative disease, stroke, and amyotrophic lateral sclerosis.¹⁸ A review of the literature on medical treatment of sialorrhea found that Botox is probably effective for the treatment of this condition (Level B evidence).²⁴

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Botox. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Botox as well as the monitoring required for adverse events and long-term efficacy, approval for a diagnosis of migraine headache prevention requires Botox to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Prescription benefit coverage is not recommended for Botox Cosmetic or cosmetic conditions.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Botox is recommended in those who meet one of the following criteria:

FDA-Approved Indications

1. **Blepharospasm.** Approve for 1 year if the patient is ≥ 12 years of age.
Note: This includes blepharospasm associated with dystonia, benign essential blepharospasm, seventh (VII) nerve disorders.
2. **Cervical Dystonia.** Approve for 1 year if the patient is ≥ 18 years of age.
Note: Cervical dystonia is also referred to as spasmodic torticollis.
3. **Hyperhidrosis, Primary Axillary.** Approve for 1 year if the patient meets ALL of the following (A, B, C, and D):
 - A) Patient is ≥ 18 years of age; AND
 - B) Hyperhidrosis is significantly interfering with the ability to perform age-appropriate activities of daily living; AND
 - C) The prescriber has excluded secondary causes of hyperhidrosis; AND
 - D) Patient has tried at least one topical prescription agent for axillary hyperhidrosis for at least 4 weeks and experienced inadequate efficacy or significant intolerance.
Note: Examples of prescription topical agents for the treatment of axillary hyperhidrosis include Xerac AC (aluminum chloride 6.25% topical solution), Drysol (aluminum chloride 20% topical solution), Qbrexza (glycopyrronium cloth 2.4% for topical use), Sofdra (glycopyrronium 12.45% topical gel).
4. **Migraine Headache Prevention.** Approve for 1 year if the patient meets ALL of the following (A, B, C, and D):
 - A) Patient is ≥ 18 years of age; AND
 - B) Patient has ≥ 15 migraine headache days per month with headache lasting 4 hours per day or longer (prior to initiation of Botox therapy); AND
 - C) Botox is being prescribed by or in consultation with a neurologist or headache specialist; AND
 - D) If the patient is currently taking Botox for migraine headache prevention, the patient has had a significant clinical benefit from the medication as determined by the prescriber.

Note: Examples of significant clinical benefit include a reduction in the overall number of migraine days per month or a reduction in number of severe migraine days per month from the time that Botox was initiated.

5. **Neurogenic Detrusor Overactivity (NDO), Pediatric.** Approve for 1 year if the patient meets BOTH of the following (A and B):

A) Patient is ≥ 5 years of age; AND

B) Patient has tried at least one other pharmacologic therapy for the treatment of neurogenic detrusor overactivity (NDO).

Note: Examples of other NDO pharmacologic therapies include a beta-3 adrenergic agonist or an anticholinergic medication. For treatment of adult urinary incontinence due to detrusor overactivity associated with a neurological condition, refer to the FDA-Approved Indication below.

6. **Overactive Bladder with Symptoms of Urge Urinary Incontinence, Urgency, and Frequency (Adult).** Approve for 1 year if the patient meets BOTH of the following (A and B):

A) Patient is ≥ 18 years of age; AND

B) Patient has tried at least one other pharmacologic therapy for the treatment of overactive bladder (OAB).

Note: Examples of other OAB pharmacologic therapies include a beta-3 adrenergic agonist or an anticholinergic medication. For treatment of adult urinary incontinence due to detrusor overactivity associated with a neurological condition, refer to the FDA-Approved Indication below.

7. **Spasticity, Limb(s).** Approve for 1 year if the is patient ≥ 2 years of age.

8. **Strabismus.** Approve for 1 year if the patient is ≥ 12 years of age.

Note: Common types of strabismus include esotropia, exotropia, hypertropia, hypotropia.

9. **Urinary Incontinence Due to Detrusor Overactivity Associated with a Neurological Condition (Adult).** Approve for 1 year if the patient meets BOTH of the following (A and B):

Note: Examples of neurological conditions associated with urinary incontinence include spinal cord injury, multiple sclerosis, spina bifida.

A) Patient is ≥ 18 years of age; AND

B) Patient has tried at least one other pharmacologic therapy for the treatment of urinary incontinence.

Note: Examples of other pharmacologic therapies for urinary incontinence include a beta-3 adrenergic agonist or an anticholinergic medication. For treatment of adult overactive bladder with symptoms of urge urinary incontinence, urgency, and frequency, refer to the FDA-Approved Indications above. For treatment of pediatric neurogenic detrusor overactivity (NDO), refer to the FDA-Approved Indication above.

Other Uses with Supportive Evidence

10. **Achalasia.** Approve for 1 year if the patient is ≥ 18 years of age.

Note: Achalasia is also referred to as esophageal achalasia or achalasia cardia.

11. **Anal Fissure, Chronic.** Approve for 1 year if the patient is ≥ 18 years of age.

12. **Dystonia, Focal Upper Limb.** Approve for 1 year if the patient is ≥ 18 years of age.

Note: An example of focal upper limb dystonia is focal hand dystonia.

- 13. Essential Tremor.** Approve for 1 year if the patient meets BOTH of the following (A and B):
- A) Patient is ≥ 18 years of age; AND
 - B) Patient has tried at least one other pharmacologic therapy for the treatment of tremors.
- Note: Examples of pharmacologic therapies for essential tremor include primidone, propranolol, atenolol, sotalol, alprazolam, gabapentin, or topiramate.
- 14. Hemifacial Spasm.** Approve for 1 year if the patient is ≥ 18 years of age.
- 15. Hyperhidrosis, Gustatory.** Approve for 1 year if the patient is ≥ 18 years of age.
- Note: Gustatory hyperhidrosis is also referred to as Frey's Syndrome.
- 16. Hyperhidrosis, Primary Palmar/Plantar/Facial.** Approve for 1 year if the patient meets ALL of the following (A, B, C and D):
- A) Patient is ≥ 18 years of age; AND
 - B) Hyperhidrosis is significantly interfering with the ability to perform age-appropriate activities of daily living; AND
 - C) The prescriber has excluded secondary causes of hyperhidrosis; AND
 - D) Patient has tried at least one topical agent for the treatment of hyperhidrosis for at least 4 weeks and experienced inadequate efficacy or significant intolerance.
- Note: Examples of topical agents for the treatment of hyperhidrosis include topical aluminum chloride antiperspirants.
- 17. Laryngeal Dystonia (Spasmodic Dysphonia).** Approve for 1 year if the patient is ≥ 18 years of age.
- 18. Oromandibular Dystonia.** Approve for 1 year if the patient is ≥ 18 years of age.
- Note: Oromandibular dystonia is also referred to as orofacial dystonia.
- 19. Sialorrhea, Chronic.** Approve for 1 year if the patient is ≥ 18 years of age.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Botox is not recommended in the following situations:

- 1. Cosmetic Uses.** Cosmetic use is not recommended for coverage as this indication is excluded from coverage in a typical pharmacy benefit.
- Note: Examples of cosmetic uses include facial rhytides, frown lines, glabellar wrinkling, horizontal neck rhytides, mid and lower face and neck rejuvenation, platysmal bands, or rejuvenation of the periorbital region.
- 2. Gastroparesis.** The ACG issued clinical guidelines on the management of gastroparesis (2013).²⁶ ACG does not recommend the use of botulinum toxin injected into the pylorus as a treatment for gastroparesis. This is based on two double-blind, placebo-controlled studies which did show some improvement in gastric emptying, but no improvement in symptoms compared with placebo.
- 3.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Botulinum Toxin – Daxxify Prior Authorization Policy

- Daxxify® (daxibotulinumtoxinA-lanm injection – Revance)

REVIEW DATE: 09/25/2024

OVERVIEW

Daxxify (daxibotulinumtoxinA-lanm), an acetylcholine release inhibitor and neuromuscular-blocking agent, is indicated for the following use:¹

- **Cervical dystonia** in adults.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Daxxify. All approvals are provided for the duration noted below.

Prior Authorization and prescription benefit are not recommended for cosmetic conditions.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Daxxify is recommended in those who meet the following criteria:

FDA-Approved Indication

1. **Cervical Dystonia.** Approve for 1 year if the patient is ≥ 18 years of age.

Note: Cervical dystonia is also known as spasmodic torticollis.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Daxxify is not recommended in the following situations:

4. **Cosmetic Uses.** Cosmetic use is not recommended for coverage as this indication is excluded from coverage in a typical pharmacy benefit.

Note: Examples of cosmetic uses include facial rhytides, frown lines, glabellar wrinkling, horizontal neck rhytides, mid and lower face and neck rejuvenation, platysmal bands, or rejuvenation of the periorbital region.

5. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Botulinum Toxin – Dysport Prior Authorization Policy

- Dysport® (abobotulinumtoxinA injection – Ipsen/Galderma)

REVIEW DATE: 10/02/2024

OVERVIEW

Dysport (abobotulinumtoxinA), an acetylcholine release inhibitor and neuromuscular-blocking agent, is indicated for the following uses:¹

- **Cervical dystonia** in adults.
- **Spasticity** in patients ≥ 2 years of age.

Other Uses with Supportive Evidence

Botulinum toxins have been studied in a variety of indications outside of FDA-approved uses.²⁻⁴ Literature is available to support use of Dysport in the following conditions:

- **Anal Fissure:** The American College of Gastroenterology (ACG) clinical guideline for the management of benign anorectal disorders (2021) suggests that botulinum toxin A injections (formulation not specified) may be attempted for patients with chronic anal fissures in whom calcium channel blockers fail or as an alternative option to calcium channel blockers (conditional recommendation; quality of evidence low).⁵ Dysport was also found to be more effective than isosorbide dinitrate ointment as the primary treatment for chronic anal fissures in a randomized, multicenter 4 year clinical trial.²¹
- **Blepharospasm:** Dysport has demonstrated efficacy in clinical trials in patients with blepharospasm.^{6,7} American Academy of Neurology (AAN) guidelines (2016, reaffirmed 2022) support the use of Dysport for blepharospasm with a Level C recommendation (“possibly effective”).⁸ An evidenced-based review and assessment (2013) for the treatment of blepharospasm indicate Dysport should be considered (Level B recommendation).²⁰ Of note, Meige syndrome is a variant that describes the co-existence of blepharospasm and oromandibular dystonia.¹⁴
- **Hemifacial Spasm:** Per historical AAN guidelines for the treatment of movement disorders, botulinum toxin (formulation not specified) may be considered in hemifacial spasm (Level C recommendation).⁹ Data with Botox® (onabotulinumtoxinA injection) and Dysport are cited in the recommendations regarding hemifacial spasm. An evidenced-based review and assessment (2013) for the treatment of hemifacial spasm indicate Botox® (onabotulinumtoxinA injection) should be considered (Level B recommendation) and Dysport may be considered (Level C recommendation).²⁰
- **Oromandibular Dystonia:** Small clinical trials have shown botulinum toxin A to be effective in treating oromandibular dystonia.^{10,11} The American Academy of Oral Medicine clinical practice statement on oromandibular dystonia recommend the use of botulinum type A injections (Botox is mentioned).¹² A five year trial with Dysport for the treatment of focal movement disorders including oromandibular dystonia showed effectiveness and no new safety concerns.¹³ An evidence-based review and assessment (2013) for the treatment of oromandibular dystonia indicate Botox and Dysport may be considered (level C recommendation).²⁰ Of note, Meige syndrome is a variant that describes the co-existence of blepharospasm and oromandibular dystonia.¹⁴
- **Sialorrhea:** Botulinum toxin A has been studied in the treatment of sialorrhea associated with Parkinson’s Disease, parkinsonian syndromes, cerebral palsy, head and neck carcinoma, neurodegenerative disease, stroke, and amyotrophic lateral sclerosis.² A review of the literature

10/02/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

on medical treatment of sialorrhea found that Dysport is probably effective for the treatment of this condition (Level B evidence).¹⁵

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Dysport. All approvals are provided for 1 year in duration.

Prescription benefit coverage is not recommended for cosmetic conditions.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Dysport is recommended in those who meet one of the following criteria:

FDA-Approved Indications

2. **Cervical Dystonia.** Approve for 1 year if the patient is ≥ 18 years of age.
Note: Cervical dystonia is also referred to as spasmodic torticollis.
3. **Spasticity, Limb(s).** Approve for 1 year if the patient is ≥ 2 years of age.

Other Uses with Supportive Evidence

4. **Anal Fissure, Chronic.** Approve for 1 year if the patient is ≥ 18 years of age.
5. **Blepharospasm.** Approve for 1 year if the patient is ≥ 18 years of age.
Note: This includes blepharospasm associated with dystonia, benign essential blepharospasm, seventh (VII) nerve disorders.
6. **Hemifacial Spasm.** Approve for 1 year if the patient is ≥ 18 years of age.
7. **Oromandibular Dystonia.** Approve for 1 year if the patient is ≥ 18 years of age.
Note: Oromandibular dystonia is also referred to as orofacial dystonia.
8. **Sialorrhea, Chronic.** Approve for 1 year if the patient is ≥ 18 years of age.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Dysport is not recommended in the following situations:

6. **Cosmetic Uses.** Cosmetic use is not recommended for coverage as this indication is excluded from coverage in a typical pharmacy benefit.
Note: Examples of cosmetic uses include facial rhytides, frown lines, glabellar wrinkling, horizontal neck rhytides, mid and lower face and neck rejuvenation, platysmal bands, or rejuvenation of the periorbital region.
7. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Botulinum Toxins – Myobloc Prior Authorization Policy

- Myobloc® (rimabotulinumtoxinB injection – Solstice Neurosciences)

REVIEW DATE: 9/25/2024

OVERVIEW

Myobloc (rimabotulinumtoxinB), an acetylcholine release inhibitor and neuromuscular-blocking agent, is indicated for the following uses:¹

- **Cervical dystonia** in adults.
- **Sialorrhea, chronic** in adults.

Other Uses with Supportive Evidence

Spasticity, Upper Limb(s): In the 2016 American Academy of Neurology guidelines (reaffirmed 2022), Myobloc is supported for use in adult upper limb spasticity (Level B; probably effective).² Of note, evidence is insufficient for Myobloc in the setting of lower limb spasticity (Level U).

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Myobloc. All approvals are provided for the duration noted below.

Prior Authorization and prescription benefit coverage are not recommended for cosmetic conditions.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Myobloc is recommended in those who meet one of the following criteria:

FDA-Approved Indications

1. **Cervical Dystonia.** Approve for 1 year if the patient is ≥ 18 years of age.
Note: Cervical dystonia is also known as spasmodic torticollis.
2. **Sialorrhea, Chronic.** Approve for 1 year if the patient is ≥ 18 years of age.

Other Uses with Supportive Evidence

3. **Spasticity, Upper Limb(s).** Approve for 1 year if the patient is ≥ 18 years of age.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Myobloc is not recommended in the following situations:

1. **Cosmetic Uses.** Cosmetic use is not recommended for coverage as this indication is excluded from coverage in a typical pharmacy benefit.

01/24/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Note: Examples of cosmetic uses include facial rhytides, frown lines, glabellar wrinkling, horizontal neck rhytides, mid and lower face and neck rejuvenation, platysmal bands, or rejuvenation of the periorbital region.

2. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Botulinum Toxins – Xeomin Prior Authorization Policy

- Xeomin® (incobotulinumtoxinA injection – Merz)

REVIEW DATE: 10/02/2024

OVERVIEW

Xeomin (incobotulinumtoxinA), an acetylcholine release inhibitor and neuromuscular-blocking agent, is indicated for the following uses:¹

- **Blepharospasm** in adults.
- **Cervical dystonia** in adults.
- **Sialorrhea, chronic**, in patients ≥ 2 years of age.
- **Upper limb spasticity:**
 - In adults.
 - In pediatric patients ≥ 2 years of age, excluding spasticity caused by cerebral palsy.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Xeomin. All approvals are provided for the duration noted below.

Prescription benefit coverage is not recommended for cosmetic conditions.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Xeomin is recommended in those who meet one of the following criteria:

FDA-Approved Indications

- 9. Blepharospasm.** Approve for 1 year if the patient is ≥ 18 years of age.
Note: This includes blepharospasm associated with dystonia, benign essential blepharospasm, seventh (VII) nerve disorders.
- 10. Cervical Dystonia.** Approve for 1 year if the patient is ≥ 18 years of age.
Note: Cervical dystonia is also known as spasmodic torticollis.
- 11. Sialorrhea, Chronic.** Approve for 1 year if the patient is ≥ 2 years of age.
- 12. Spasticity, Upper Limb(s).** Approve for 1 year if the patient is ≥ 2 years of age.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Xeomin is not recommended in the following situations:

10/02/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- 8. Cosmetic Uses.** Cosmetic use is not recommended for coverage as this indication is excluded from coverage in a typical pharmacy benefit.

Note: Examples of cosmetic uses include facial rhytides, frown lines, glabellar wrinkling, horizontal neck rhytides, mid and lower face and neck rejuvenation, platysmal bands, or rejuvenation of the periorbital region.

- 9.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Cardiology – Camzyos Prior Authorization Policy

- Camzyos® (mavacamten capsules – MyoKardia/Bristol Myers Squibb)

REVIEW DATE: 06/05/2024

OVERVIEW

Camzyos, a cardiac myosin inhibitor, is indicated for the treatment of symptomatic New York Heart Association Class (NYHA) II to III **obstructive hypertrophic cardiomyopathy** in adults to improve functional capacity and symptoms.

Disease Overview

Hypertrophic cardiomyopathy is a complex myocardial disorder in which the walls of the heart muscle, more specifically the left ventricle, are thickened or hypertrophied.²⁻⁵ The condition is inherited in an autosomal dominant pattern. The estimated prevalence is one in 200 to 500 adults. Patients of any age can be impacted. However, many patients may be undiagnosed or be asymptomatic. Diagnoses is usually by echocardiographic or magnetic resonance imaging which reveals a hypertrophied, nondilated left ventricle without another identifiable cardiac, systemic, metabolic or syndromic disease. The left ventricle becomes stiff, which makes it more difficult for the heart to normally expand and fill with blood. The amount of blood that the left ventricle can hold and pump throughout the body is reduced; the hypertrophied heart muscle may also pump with too much force. Many patients with hypertrophic cardiomyopathy have obstructive disease in which the path for blood flow out of the heart can narrow and the output to the rest of the body may be restricted which is referred to as left ventricular outflow tract obstruction. This forces the heart to pump harder to overcome the obstructive forces. Symptoms that are commonly present with hypertrophic cardiomyopathy include shortness of breath, palpitations, light headedness, chest pain, fatigue, and exercise intolerance. Many patients have heart failure, as well as atrial fibrillation or other ventricular arrhythmias. Sudden death may also result. Hypertrophic cardiomyopathy is due to enhanced interactions between two cardiac proteins, actin and myosin. Camzyos works by reducing the number of intersections formed between actin and myosin which leads to more optimized heart relaxation and filling; lessened heart muscle workload during contractions; and improved efficiency in energy utilized for each heartbeat. Before approval of Camzyos, treatment for obstructive hypertrophic cardiomyopathy focused on symptomatic relief with medications such as beta blockers, non-dihydropyridine calcium channel blockers (CCBs), and disopyramide. Septal reduction therapy is an option.

Clinical Efficacy

EXPLORER-HCM was a randomized, double-blind, placebo-controlled, parallel-group trial that evaluated Camzyos in over 250 patients with symptomatic NYHA Class II or III obstructive hypertrophic cardiomyopathy.^{1,2} Patients had a left ventricular ejection fraction $\geq 55\%$ and a left ventricular outflow tract peak gradient ≥ 50 mmHg (at rest or with provocation [Valsalva maneuver or post exercise]). Unexplained left ventricular hypertrophy was present with maximal left ventricular wall thickness of ≥ 15 mm or ≥ 13 mm if the patient had familial hypertrophic cardiomyopathy.² Approximately 75% of patients were receiving beta blockers and 17% of patients were on CCBs for symptoms. The primary composite functional endpoint, evaluated at 30 weeks, was defined as the proportion of patients who achieved either improvement of mixed venous oxygen tension/peak oxygen consumption (pVO_2) by ≥ 1.5 mL/kg/min plus improvement in NYHA class by at least one or improvement of pVO_2 by ≥ 3.0 mL/kg/min plus no worsening in NYHA class. A greater proportion of patients receiving Camzyos met this composite endpoint compared with patients given placebo (37% vs. 17%, respectively; $P = 0.0005$). Regarding secondary

06/05/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

endpoints, Camzyos led to greater improvements compared with placebo in measures assessing left ventricular outflow tract (LVOT) obstruction, functional capacity, and health status. These parameters were assessed by change from baseline through Week 30 in post-exercise LVOT peak gradient, change in pVO₂, proportion of patients with improvement in NYHA class, Kansas City Cardiomyopathy Questionnaire-23 (KCCQ-23) Clinical Summary Score (CSS), and Hypertrophic Cardiomyopathy Symptoms Questionnaire (HCMSQ) Shortness of Breath domain score.^{1,2} At Week 30, there were also reductions in N-terminal pro B-type natriuretic peptide and high-sensitivity cardiac troponin I levels from baseline.² Other data are also available.⁶

Guidelines

Guidelines have not incorporated Camzyos.

- **Hypertrophic Cardiomyopathy:** In 2020, the American Heart Association and the American College of Cardiology published guidelines for the diagnosis and treatment of patients with hypertrophic cardiomyopathy.⁷ For symptomatic patients with obstructive hypertrophic cardiomyopathy attributable to LVOT obstruction, nonvasodilating beta blockers are recommended to be titrated to effectiveness or maximally tolerated doses. In patients for whom beta blockers are not effective or not tolerated, substitution with nondihydropyridine CCBs (e.g., verapamil, diltiazem) is recommended. If the patient continues to have persistent severe symptoms despite beta blocker therapy or CCBs, either adding disopyramide in combination with one of the other drugs is recommended. Also, septal reduction therapy, performed at experienced centers, is an option for selected patients. One of the other key steps in managing symptomatic, obstructive hypertrophic cardiomyopathy is to eliminate medication that may promote outflow tract obstruction like pure vasodilators (e.g., dihydropyridine CCBs, angiotensin converting enzyme inhibitors, angiotensin receptor blockers) and high-dose diuretics. Low-dose diuretics, when added to other first-line medications, may be useful for patients with persistent dyspnea or congestive symptoms.

Safety

Camzyos has a Boxed Warning regarding the risk of heart failure.¹ The agent may cause heart failure due to systolic dysfunction. Echocardiogram assessment of left ventricular ejection fraction is required before and during Camzyos use. Initiation in patients with a left ventricular ejection fraction < 55% is not recommended. Therapy should be interrupted if left ventricular ejection fraction is less than 50% or if worsening clinical status occurs. Certain cytochrome P450 inhibitors and inducers are contraindicated in patients receiving Camzyos due to an increased risk of heart failure. Camzyos is available only through a restricted program called the Camzyos Risk Evaluation and Mitigation Strategy (REMS) program. Notable requirements include the following:

- Prescribers must be certified by enrolling in the Camzyos REMS program.
- Patients must enroll in the Camzyos REMS program and comply with ongoing monitoring requirements.
- Pharmacies must be certified by enrolling in the Camzyos REMS program and must only dispense to patients who are authorized to receive Camzyos.
- Wholesalers and distributors must only distribute the medication to certified pharmacies.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Camzyos. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Camzyos as well as the monitoring required for adverse events and long-term efficacy, approval requires Camzyos to be prescribed by a physician who specializes in the condition being treated.

06/05/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Camzyos is recommended in those who meet the following criteria:

FDA-Approved Indication

10. Obstructive Hypertrophic Cardiomyopathy. Approve for the duration noted below if the patient meets ONE of the following (A or B):

A) Initial Therapy. Approve for 8 months if the patient meets ALL of the following (i, ii, iii, iv, v, and vi):

i. Patient is ≥ 18 years of age; AND

ii. Patient meets BOTH of the following (a and b):

a) Patient has at least one symptom associated with obstructive hypertrophic cardiomyopathy; AND

Note: Examples of symptoms include shortness of breath, chest pain, lightheadedness, fainting, fatigue, and reduced ability to perform physical exercise.

b) Patient has New York Heart Association Class II or III symptoms of heart failure; AND

Note: Class II signifies mild symptoms with moderate physical activity and some exercise limitations whereas Class III denotes noticeable symptoms with minimal physical activity and patients are only comfortable at rest.

iii. Patient with left ventricular hypertrophy meets ONE of the following (a or b):

a) Patient has maximal left ventricular wall thickness ≥ 15 mm; OR

b) Patient has familial hypertrophic cardiomyopathy with a maximal left ventricular wall thickness ≥ 13 mm; AND

iv. Patient has a peak left ventricular outflow tract gradient ≥ 50 mmHg (at rest or after provocation [Valsalva maneuver or post exercise]); AND

v. Patient has a left ventricular ejection fraction of $\geq 55\%$; AND

vi. The medication is prescribed by a cardiologist; OR

B) Patient Currently Receiving Camzyos. Approve for 1 year if the patient meets ALL of the following (i, ii, iii, iv, v and vi):

i. Patient has been established on therapy for at least 8 months; AND

Note: A patient who has received < 8 months of therapy or who is restarting therapy is reviewed under criterion A (Initial Therapy).

ii. Patient is ≥ 18 years of age; AND

iii. Patient meets BOTH of the following (a and b):

a) Currently or prior to starting therapy, patient has or has experienced at least one symptom associated with obstructive hypertrophic cardiomyopathy; AND

Note: Examples of symptoms include shortness of breath, chest pain, lightheadedness, fainting, fatigue, and reduced ability to perform physical exercise.

b) Currently or prior to starting therapy, patient is in or was in New York Heart Association Class II or III heart failure; AND

Note: Class II signifies mild symptoms with moderate physical activity and some exercise limitations whereas Class III denotes noticeable symptoms with minimal physical activity and patients are only comfortable at rest.

iv. Patient has a current left ventricular ejection fraction of $\geq 50\%$; AND

v. Patient meets ONE of the following (a or b):

a) Patient experienced a beneficial clinical response when assessed by at least one objective measure; OR

Note: Examples include improved peak oxygen consumption/mixed venous oxygen tension; decreases in left ventricular outflow tract gradient; reductions in N-terminal pro-B-type natriuretic peptide levels; decreased high-sensitivity cardiac troponin I levels; reduced ventricular mass index; and/or a reduction in maximum left atrial volume index.

- b) Patient experienced stabilization or improvement in at least one symptom related to obstructive hypertrophic cardiomyopathy; AND

Note: Examples of symptoms include shortness of breath, chest pain, lightheadedness, fainting, fatigue, ability to perform physical exercise, and/or favorable changes in the Kansas City Cardiomyopathy Questionnaire-23 (KCCQ-23) Clinical Summary Score (CSS) or Hypertrophic Cardiomyopathy Symptom Questionnaire (HCMSQ) Shortness of Breath domain scores.

- vi. The medication is prescribed by a cardiologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Camzyos is not recommended in the following situations:

57. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Cardiology – Ivabradine Prior Authorization Policy

- Corlanor® (ivabradine tablets and oral solution – Amgen, generic [tablets only])

REVIEW DATE: 08/14/2024

OVERVIEW

Ivabradine, a hyperpolarization-activated cyclic nucleotide-gated channel blocker, is indicated for the following uses:¹

- **Heart failure, in adults**, to reduce the risk of hospitalization for worsening of the disease in those with stable, symptomatic chronic heart failure with left ventricular ejection fraction (LVEF) $\leq 35\%$, who are in sinus rhythm with a resting heart rate ≥ 70 beats per minute (bpm) and either are receiving maximally tolerated doses of beta blockers or have a contraindication to beta blocker use.
- **Heart failure, in pediatric patients ≥ 6 months and older**, for treatment of stable symptomatic disease due to dilated cardiomyopathy, among those who are in sinus rhythm with an elevated heart rate.

Data are available with ivabradine that note improvement in symptoms and increased exercise performance in patients with inappropriate sinus tachycardia, defined as a sinus heart rate > 100 bpm at rest (with a mean 24-hour heart rate > 90 bpm not due to primary causes) which is generally associated with distressing symptoms such as palpitations, weakness, dizziness and syncope.²⁻⁹ Beta blockers have also been used for this condition. Limited data are available for other treatments that have been used and/or effectiveness have not been established (e.g., beta blockers, fludrocortisone, volume expansion, clonidine, and erythropoietin).

Guidelines

A few guidelines have recommendations that involve ivabradine.

- **Heart Failure:** The American Heart Association/American College of Cardiology/Heart Failure Society of America published guidelines in 2022 for the management of heart failure.¹⁰ For patients with symptomatic (New York Heart Association Class II to III) stable chronic heart failure with reduced ejection fraction (LVEF $\leq 35\%$) who are receiving guideline-directed medical therapy, including a beta blocker at maximum tolerated dose, and who are in sinus rhythm with a heart rate of ≥ 70 beats per minute at rest, ivabradine can be beneficial to reduce heart failure hospitalizations and cardiovascular death.
- **Inappropriate Sinus Tachycardia:** The 2015 Heart Rhythm Society Expert Consensus Statement on the diagnosis and treatment of postural tachycardia syndrome, inappropriate sinus tachycardia, and vasovagal syncope state that ivabradine can be useful for treating patients with inappropriate sinus tachycardia.² Additionally, the 2015 American College of Cardiology, American Heart Association Task Force on Clinical Practice Guidelines, and the Heart Rhythm Society also state that ivabradine is reasonable for ongoing management in patients with symptomatic inappropriate sinus tachycardia (class IIa recommendation).³ Beta blockers may be considered for ongoing management in patients with symptomatic inappropriate sinus tachycardia (class IIb recommendation). Also, the guidelines state that the combination of beta blockers and ivabradine may be considered for the ongoing management of patients with inappropriate sinus tachycardia (class IIb recommendation).

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of ivabradine. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with ivabradine as well as the monitoring required for adverse events and long-term efficacy, approval requires ivabradine to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of ivabradine is recommended in those who meet one of the following criteria:

FDA-Approved Indications

- 11. Heart Failure.** Approve for 1 year if the patient meets ALL of the following (A, B, C, D, and E):
 - C) Patient is ≥ 18 years of age; AND
 - D) Patient has a left ventricular ejection fraction (LVEF) $\leq 35\%$ currently or prior to initiation of ivabradine therapy; AND
 - E) Patient is in normal sinus rhythm or sinus tachycardia with a resting heart rate of ≥ 70 beats per minute; AND
 - F) Patient meets ONE of the following (i or ii):
 - i. Patient has tried or is currently receiving one beta blocker for heart failure treatment; OR
Note: Examples of beta blockers are metoprolol succinate sustained-release, carvedilol, bisoprolol, and Coreg CR (carvedilol extended-release capsules).
 - ii. Patient has a contraindication to use of beta blocker therapy; AND
Note: Examples that are contraindications to use of beta blockers are bronchospastic disease such as chronic obstructive pulmonary disease and asthma, severe hypotension or bradycardia.
 - G) The medication is prescribed by or in consultation with a cardiologist.
- 2. Heart Failure due to Dilated Cardiomyopathy in Pediatric Patients.** Approve for 1 year if the patient meets BOTH of the following (A and B):
 - A) Patient is < 18 years of age; AND
 - B) The medication is prescribed by or in consultation with a cardiologist.

Other Uses with Supportive Evidence

- 3. Inappropriate Sinus Tachycardia.** Approve for 1 year if the patient meets BOTH of the following (A and B):
 - A) Patient meets ONE of the following (i or ii):
 - i. Patient has tried or is currently receiving one beta blocker for inappropriate sinus tachycardia; OR
Note: Examples of beta blockers are metoprolol and bisoprolol.
 - ii. Patient has a contraindication to use of beta blocker therapy; AND
Note: Examples that are contraindications to use of beta blockers are bronchospastic disease such as chronic obstructive pulmonary disease and asthma, severe hypotension or bradycardia.
 - B) The medication is prescribed by or in consultation with a cardiologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of ivabradine is recommended in those who meet the following criteria:

- 58. Stable Angina Pectoris, in Patients Without Chronic Heart Failure.** Ivabradine has been studied as a treatment for stable angina pectoris but further data are needed.¹¹⁻¹³ The 2023 American Heart Association/American College of Cardiology guidelines for chronic coronary disease (CCD) state that in patients with CCD and normal left ventricular function, the addition of ivabradine to standard anti-anginal therapy is potentially harmful.¹⁴
- 59.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Cardiology – Lodoco Prior Authorization Policy

- Lodoco® (colchicine 0.5 mg tablets – Agepha)

REVIEW DATE: 08/21/2024

OVERVIEW

Lodoco, an alkaloid, is indicated to reduce the risk of myocardial infarction (MI), stroke, coronary revascularization, and cardiovascular (CV) death in adults with established atherosclerotic disease or with multiple risk factors for CV disease.¹ The safety and effectiveness have not been established in pediatric patients.

Clinical Efficacy

The efficacy of Lodoco was evaluated in one, double-blind, placebo-controlled, event-driven, investigator-initiated, pivotal study called LoDoCo2 involving 5,522 adults with chronic stable coronary disease who received Lodoco 0.5 mg once daily or matching placebo.^{1,2} The mean patient age was 66 years; only 15% of patients were female. Patients had an estimated glomerular filtration rate ≥ 50 mL/min. An acute coronary syndrome event had occurred previously in 84% of patients. Most patients were also receiving standard of care therapy for secondary prevention of CV events. Examples of medications utilized for chronic coronary disease included antiplatelet agents or an anticoagulant (99.7%), a lipid-lowering agent (96.6% [mostly statins]), a renin-angiotensin system inhibitor (71.7%), and beta-blockers (62.1%). The median time on study medication was 28.6 months. A primary endpoint event (a composite of CV death, MI, ischemic stroke, or ischemia-driven coronary revascularization) occurred in 6.8% of patients randomized to Lodoco vs. 9.6% of patients receiving placebo (hazard ratio 0.69; $P < 0.001$).

Guidelines

Guidelines for the management of patients with chronic coronary disease from the American Heart Association and the American College of Cardiology (2023) state that in patients with chronic coronary disease, the addition of colchicine for secondary prevention may be considered to reduce recurrent atherosclerotic cardiovascular disease events (Class of Recommendation: 2b [weak] {benefit $\geq$ risk}; Level of Evidence: randomized).³

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Lodoco. All approvals are provided for the duration noted below.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Lodoco is recommended in those who meet the following criteria:

08/21/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

FDA-Approved Indication

29. Atherosclerotic Disease. Approve for 1 year if the patient meets the following (A, B, C, D, and E):

- A) Patient is ≥ 18 years of age; AND
- B) Patient has had one of the following conditions or diagnoses (i, ii, iii, iv, v, or vi):
 - i. A previous myocardial infarction or a history of an acute coronary syndrome; OR
 - ii. Angina (stable or unstable); OR
 - iii. A past of stroke or transient ischemic attack; OR
 - iv. Coronary artery disease; OR
 - v. Peripheral arterial disease; OR
 - vi. Patient has undergone a coronary or other arterial revascularization procedure in the past; AND
Note: Examples include coronary artery bypass graft surgery, percutaneous coronary intervention, angioplasty, and coronary stent procedures.
- C) Lodoco is being added onto other background regimens of other atherosclerotic disease medications according to the prescriber; AND
Note: Examples of medications recommended in guideline-directed therapy for patients with atherosclerotic disease can include aspirin, antiplatelet agents (e.g., clopidogrel, Brilinta [ticagrelor tablets]), anticoagulants, lipid-lowering agents (e.g., statins such as atorvastatin and rosuvastatin), beta blockers, angiotensin-converting enzyme inhibitors, and/or angiotensin receptor blockers.
- D) Patient does not have severe hepatic impairment according to the prescriber; AND
- E) Patient has a creatinine clearance ≥ 50 mL/min.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Lodoco is not recommended in the following situations:

29. Primary Prevention of Cardiovascular Events. Guidelines for the primary prevention of cardiovascular disease do not currently address Lodoco.⁴ Most patients in the pivotal trial with Lodoco had past cardiovascular events or had undergone a coronary or other arterial revascularization procedure in the past.²

30. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Cardiology – Tryvio Prior Authorization Policy

- Tryvio™ (aprocitentan tablets – Idorsia)

REVIEW DATE: 08/14/2024; selected revision 12/04/2024

OVERVIEW

Tryvio, an endothelin receptor antagonist, is indicated for the treatment of hypertension in combination with other antihypertensive medications, to lower blood pressure in adults who are not adequately controlled on other drugs.¹ Lowering blood pressure reduces the risk of fatal and non-fatal cardiovascular events, primarily strokes and myocardial infarctions.

Guidelines

Guidelines have not addressed Tryvio. Guidelines are available for the management of hypertension in adults. There are many medications available for the management of hypertension.² These include thiazide-like diuretics (e.g., chlorthalidone, hydrochlorothiazide, metolazone), potassium-sparing diuretics (e.g., amiloride, triamterene), mineralocorticoid receptor antagonists (e.g., spironolactone, eplerenone), angiotensin converting enzyme (ACE) inhibitors (e.g., enalapril, lisinopril, ramipril, trandolapril), angiotensin receptor blockers (ARBs) [e.g., candesartan, irbesartan, valsartan], a direct renin inhibitor (i.e., aliskiren), dihydropyridine calcium channel blockers (CCBs) [e.g., felodipine, amlodipine], non-dihydropyridine CCBs (e.g., diltiazem, verapamil), beta blockers (e.g., atenolol, bisoprolol, metoprolol, acebutolol), alpha-adrenergic blockers (e.g., doxazosin, prazosin, terazosin), central alpha-adrenergic agonists (e.g., clonidine, guanfacine, methyl dopa), and direct vasodilators (e.g., hydralazine, minoxidil).

- **American College of Cardiology (ACC)/American Heart Association (AHA) Guidelines for High Blood Pressure:** The ACC/AHA guideline for the prevention, detection, evaluation, and management of high blood pressure in adults (2017) cites normal blood pressure (systolic blood pressure [SBP]/diastolic blood pressure [DBP]) as < 120/80 mmHg; a SBP of 120 to 129 mmHg and a DBP > 80 mmHg is considered elevated.³ Stage 1 hypertension is denoted at SBPs of 130 to 139 mmHg and DBPs as 80 to 89 mmHg; Stage 2 hypertension is defined as a SBP/DBP ≥ 140/90 mmHg.³ The guidelines are extensive. In general, for initiation of antihypertensive drug therapy (SBP/DBP ≥ 130/80 mmHg), first-line medications are thiazide diuretics, CCBs, and ACE inhibitors or ARBs. Beta blockers are also recommended in certain clinical scenarios in patients with hypertension (e.g., patients with stable ischemic heart disease or heart failure). For resistant hypertension, consider spironolactone, if appropriate. The addition of other agents with different mechanisms of action may also be useful (e.g., hydralazine, minoxidil, doxazosin, clonidine).
- **AHA Statement on Resistant Hypertension:** In 2018, the AHA published a Scientific Statement on resistant hypertension.⁴ Resistant hypertension is defined as above goal elevated blood pressure in a patient despite the concurrent use of three antihypertensive drug classes, commonly including a long-acting CCB, a blocker of the renin-angiotensin system (ACE inhibitor or an ARB), and a diuretic. The antihypertensive drugs should be given at maximum or maximally tolerated daily doses. Resistant hypertension also includes patients whose blood pressure achieves target values with use of four or more antihypertensive medications. Management of resistant hypertension includes use of long-acting thiazide-like diuretics (chlorthalidone or indapamide), the addition of a mineralocorticoid receptor antagonist (spironolactone or eplerenone), and, if blood pressure remains elevated, the addition in a stepwise manner of antihypertensive medications with complementary mechanisms of action to lower blood pressure.

POLICY STATEMENT

08/14/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Prior Authorization is recommended for prescription benefit coverage of Tryvio. All approvals are provided for the duration noted below.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Tryvio is recommended in those who meet one of the following criteria:

FDA-Approved Indication

12. Hypertension. Approve for 1 year if the patient meets BOTH of the following (A and B):

H) Patient is ≥ 18 years of age; AND

I) Patient has tried, or is currently receiving, at least three other antihypertensive agents for the treatment of hypertension from at least three of the following pharmacological classes (i, ii, iii, iv, v, vi, vii, viii, ix, x).

Note: A combination product from two or more different classes would count as an alternative from each class.

iii.Angiotensin converting enzyme (ACE) inhibitor or angiotensin receptor blocker (ARB);

Note: Examples of ACE inhibitors include benazepril, captopril, enalapril, fosinopril, lisinopril, moexipril, perindopril, ramipril, andtrandolapril. Examples of ARBs include azilsartan, candesartan, eprosartan, irbesartan, losartan, olmesartan, telmisartan, and valsartan;

iv.Non-dihydropyridine calcium channel blocker;

Note: Examples include diltiazem and verapamil.

v.Dihydropyridine calcium channel blocker;

Note: Examples include amlodipine, felodipine, isradipine, nicardipine, nifedipine, and nisoldipine.

vi.Diuretic;

Note: Examples of thiazide diuretics include chlorthalidone, chlorothiazide, hydrochlorothiazide, indapamide, and metolazone. Examples of potassium-sparing diuretics are amiloride and triamterene.

vii.Mineralocorticoid receptor antagonist;

Note: Examples include eplerenone and spironolactone.

viii.Beta blocker;

Note: Examples of beta blockers include acebutolol, atenolol, betaxolol, bisoprolol, carvedilol, metoprolol, nadolol, nebivolol, pindolol, propranolol, and timolol.

ix.Alpha-adrenergic blocker;

Note: Examples of alpha-adrenergic blockers are doxazosin, prazosin, and terazosin.

x.Central alpha-adrenergic agonist;

Note: Examples of central alpha-adrenergic agonists are clonidine, guanfacine, and methyl dopa.

xi.Direct vasodilator;

Note: Examples of direct vasodilators are hydralazine and minoxidil.

xii.Direct renin inhibitor;

Note: An example of a direct renin inhibitor is aliskiren.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Tryvio is recommended in those who meet the following criteria:

60. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Cardiology – Zontivity Prior Authorization Policy

- Zontivity® (vorapaxar tablets – Wraser)

REVIEW DATE: 10/02/2024

OVERVIEW

Zontivity, a protease-activated receptor-1 antagonist, is indicated for the reduction of thrombotic cardiovascular (CV) events in patients with **a history of myocardial infarction (MI) or with peripheral arterial disease (PAD)**.¹ The agent has been shown to reduce the rate of a combined endpoint of cardiovascular death, MI, stroke, and urgent coronary revascularization.

Studies involving Zontivity involved adding the agent to aspirin and/or clopidogrel. Use Zontivity with aspirin and/or clopidogrel according to indicated uses or the standard of care. The clinical use of Zontivity with other antiplatelet medications is limited, as well as data involving Zontivity as the only antiplatelet agent. In a subgroup analysis of the pivotal data, patients weighing < 60 kg who received Zontivity did not have a favorable outcome regarding the primary composite endpoint of CV death, MI, stroke, or urgent coronary revascularization.^{1,2}

Guidelines

Various guidelines mention Zontivity:

- **Chronic Coronary Disease:** The guidelines for the management of patients with chronic coronary disease (2023) from the American Heart Association (AHA) and the American College of Cardiology (ACC) address Zontivity.³ It is noted that in the TRAP 2P TIMI 50 trial, at a mean follow-up of 3 years, patients with a history of MI, ischemic stroke, or PAD randomized to either Zontivity, on a background of aspirin therapy, had a reduced number of ischemic events or died from common CV causes after 3 years compared with placebo. However, patients experienced more major and intracranial bleeding.
- **Peripheral Arterial Disease:** Guidelines for the management of lower extremity peripheral arterial disease from the AHA, ACC, and other organizations state that in patients with symptomatic peripheral arterial disease, the benefit of adding Zontivity to existing antiplatelet therapy is uncertain.⁴

Safety

Zontivity has a Boxed Warning regarding the risk of bleeding.¹ Zontivity is contraindicated in patients with a history of stroke, transient ischemic attack, or intracranial hemorrhage (ICH). Antiplatelet medications, including Zontivity, increase the risk of bleeding, including ICH and fatal bleeding.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Zontivity. All approvals are provided for the duration noted below.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

10/02/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Coverage of Zontivity is recommended in patients who meet the following criteria:

FDA-Approved Indication

13. Patient with a Previous Myocardial Infarction (MI) or Peripheral Arterial Disease (PAD).

Approve for 1 year if the patient meets ALL of the following (A, B, and C):

- O)** Patient weighs ≥ 60 kg; AND
 - P)** Patient is receiving Zontivity in combination with aspirin and/or clopidogrel; AND
 - Q)** Patient has been determined by the prescriber to be at high risk for future thrombotic events.
- Note: Examples of high risk include that the patient has experienced multiple myocardial infarctions, has undergone many urgent coronary revascularization procedures, has had placement of coronary artery stents, or the patient has other concomitant diseases that increase cardiovascular risk such as diabetes.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Zontivity is not recommended in the following situations:

- 61. Acute Coronary Syndrome (ACS) that Occurred Recently (within < 14 days).** In the TRACER (Thrombin Receptor Antagonist for Clinical Event Reduction in acute coronary syndrome) study, adding Zontivity to standard therapy in those who experienced an ACS increased the risk of major bleeding and did not result in clinical benefits.
- 62. Patient with a Prior History of Stroke, Transient Ischemic Attack (TIA), or Intracranial Hemorrhage (ICH).** Zontivity is contraindicated for use in patients with a of stroke, TIA, or ICH due to an increased risk of ICH in this population.
- 63. Concurrent Use of Effient (prasugrel tablets) or Brilinta (ticagrelor tablets).** There is limited clinical experience involving use of Zontivity with antiplatelet agents (e.g., Effient, Brilinta) other than aspirin and/or clopidogrel.
- 64.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Chelating Agents – Chemet Prior Authorization Policy

- Chemet® (succimer capsules – Lannett/Recordati Rare Diseases)

REVIEW DATE: 05/01/2024

OVERVIEW

Chemet, a heavy metal chelator, is indicated for the treatment of **lead poisoning** in pediatric patients with blood lead levels > 45 mcg/dL.¹ Chemet is not indicated for prophylaxis of lead poisoning in a lead-containing environment; the use of Chemet should be accompanied by identification and removal of the source of the lead exposure. Safety and efficacy of Chemet in children < 12 months of age have not been established. The course of therapy is 19 days. If indicated, a repeat course may be given with a minimum of 2 weeks between courses, unless blood lead levels indicate the need for more prompt treatment. The chemical name for Chemet is *meso* 2,3-dimercaptosuccinic acid (DMSA).

Disease Overview

Lead, mercury, arsenic, and iron account for most cases of diagnosed heavy metal poisoning in the US.² Most cases of lead poisoning are in children who swallow lead-based paint in homes or toys; other causes include water carried through pipes made of lead or containing lead solder. Children are especially susceptible to the toxic effects of lead, which may affect the developing brain and nervous system, potentially causing lower IQs, learning difficulties, hearing loss, and behavior difficulties. In adults, lead poisoning can cause high blood pressure and kidney damage.

Treatment Recommendations

Treatment of heavy metal poisoning includes removing the patient from the source of the metal and treating the patient's symptoms.² Diagnosis includes the patient's history, symptoms, and blood or urine tests.^{2,4,5} Treatment of acute metal poisoning involves emergency care and generally requires the use of chelating agents, such as DMSA.⁶

Other Uses with Supportive Evidence

Arsenic is a naturally-occurring substance; in some areas of the world, low-level arsenic exposure occurs because of the presence of arsenic in ground water.² Accidental poisoning accounts for the majority of acute arsenic toxicity.³ The Agency for Toxic Substances and Disease Registry (ATSDR) states that patients with severe arsenic poisoning must be hospitalized.⁷ Chelation therapy can curtail the distribution of arsenic in the body and reduce the body burden. Oral chelators, such as Chemet, have been used with success. There are case reports to support the use of DMSA in acute arsenic poisoning.^{3,8} The patients' clinical status improved with DMSA therapy and urine arsenic levels decreased with therapy. Note: The chemical name, DMSA, may be used to describe the case reports in this document because it is unclear if the FDA-approved Chemet product was used.

Mercury poisoning can result from vapor inhalation, mercury ingestion, mercury injection, and absorption of mercury through the skin.⁵ Symptoms of mercury poisoning depends on the type of mercury exposure and severity of exposure: organic mercury (antiseptics, bactericidals, fungicides, insecticides), inorganic mercury (chemical laboratory work, disinfectants, explosives, fur hat processing), and elemental mercury (thermometers, batteries, dental amalgams, fluorescent lamps). The ATSDR notes that patients with serious mercury exposure must be hospitalized.⁹ Chelation should be considered for any symptomatic patient with a clear history of acute elemental mercury exposure. The decision to chelate is less clear in asymptomatic

05/01/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

patients with elevated urine mercury levels.¹⁰ Oral chelators, such as Chemet, have been used successfully for the treatment of acute mercury intoxication/poisoning.⁹ The World Health Organization (WHO) recommends that urine mercury concentration should not exceed 50 mcg/g creatinine.¹¹

Several case reports have demonstrated the effectiveness of DMSA therapy for treatment of acute mercury poisoning.¹²⁻¹⁵ All of the patients exhibited symptoms consistent with mercury poisoning and were treated in a hospital setting. DMSA therapy resulted in reduction of mercury levels and improved symptomatology.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Chemet. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Chemet as well as the monitoring required for adverse events, approval requires Chemet to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Documentation: Documentation is required for use of Chemet as noted in the criteria as **[documentation required]**. Documentation may include, but is not limited to, chart notes, prescription claims records, prescription receipts and/or other information.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Chemet is recommended in those who meet one of the following criteria:

FDA-Approved Indication

- 14. Acute Lead Poisoning.** Approve for 2 months if the patient meets ALL of the following (A, B, C, and D):
- B)** Patient is between the age of 12 months and 18 years of age; AND
 - C)** Prior to starting Chemet therapy, the patient's blood lead level was > 45 mcg/dL **[documentation required]**; AND
 - D)** Chemet is being used for treatment of acute lead poisoning and not as prophylaxis against lead poisoning in a lead-containing environment; AND
 - E)** The medication is prescribed by or in consultation with a professional experienced in the use of chelation therapy (e.g., a medical toxicologist or a poison control center specialist).

Other Uses with Supportive Evidence

- 15. Acute Arsenic Intoxication/Poisoning.** Approve for 1 month if the patient meets BOTH of the following (A and B):
- A)** Patient was recently initiated on Chemet therapy in the hospital and further treatment is needed to finish the course of therapy; AND
 - B)** The medication is prescribed by or in consultation with a professional experienced in the use of chelation therapy (e.g., a medical toxicologist or a poison control center specialist).

16. Acute Mercury Intoxication/Poisoning. Approve for 1 month if the patient meets BOTH of the following (A and B):

- A) Patient was recently initiated on Chemet therapy in the hospital and further treatment is needed to finish the course of therapy; AND
- B) The medication is prescribed by or in consultation with a professional experienced in the use of chelation therapy (e.g., a medical toxicologist or a poison control center specialist).

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Chemet is not recommended in the following situations:

65. Concomitant Use with Other Chelators (e.g., calcium disodium versenate injection [CaNa₂EDTA], dimercaprol injection [British anti-Lewisite {BAL}]).

In patients with acute lead poisoning, data on the concomitant use of Chemet with CaNa₂EDTA with or without BAL are not available and such use is not recommended.¹ Patients who have received CaNa₂EDTA with or without BAL may use Chemet for subsequent treatment after an interval of four weeks.

- 2. Chelation of Heavy Metals to Treat Chronic Medical and/or Psychiatric Conditions.** Chelation of heavy metals has been advertised as a viable treatment for numerous conditions: treatment of intermittent claudication; treatment or management of symptoms of autism; prevention or cure of neurodegenerative conditions such as Alzheimer's disease; use in Parkinson's disease; treatment of macular degeneration.² There is no evidence to show that chelators work in these conditions. Furthermore, unapproved uses of chelation therapy have resulted in harm and even death. Chelation of heavy metals is also one of several popular interventions in children with autism spectrum disorders. The FDA notes chelation therapies for the treatment of autism to be associated with significant health risks and does not approve such use.¹⁶
- 3. Chronic Arsenic Exposure.** Use of chelation therapy following chronic exposure to inorganic arsenic may accelerate metal excretion, but potential therapeutic efficacy in terms of decreased morbidity and mortality is largely unestablished.¹⁷

In a prospective, randomized-controlled trial, 21 patients with chronic arsenicosis due to drinking arsenic-contaminated subsoil water were randomized to receive DMSA (1,400 mg/day or 100 mg/m² in four divided doses for 1 week and then 1,050 mg/day or 750 mg/m² in three divided doses for 2 weeks; repeat the regimen after 3 weeks) or placebo.¹⁸ The patients had of drinking arsenic-contaminated water (50 mcg/L or ≥ 0.05 mg/L) for at least 2 years and exhibited clinical signs/symptoms of chronic arsenicosis. Similar improvement in the clinical score was observed in the DMSA and placebo groups. Furthermore, urinary arsenic excretion before treatment and at 48 hours and 72 hours post-treatment were similar between the two groups. The investigators concluded that DMSA did not result in clinical or biochemical benefit in patients with chronic arsenicosis.

In another case report involving a 39 year old woman with arsenic poisoning (urine arsenic level was 2,000 mcg/L; normal level is < 10 mcg/L), DMSA 600 mg three times a day for 45 days did not significantly affect the clearance of arsenic or clinical outcome.¹⁹ During the 45-day course, the patient stopped therapy for a total of 13 days (unknown reason).

- 4. Chronic Mercury Exposure.** The American Academy of Pediatrics notes there is no scientific evidence behind the use of chelation therapy to improve nervous system symptoms of chronic mercury toxicity.¹⁶ Use of chelation therapy following chronic exposure to inorganic mercury may accelerate metal excretion, but potential therapeutic efficacy in terms of decreased morbidity and mortality is largely unestablished.¹⁷

05/01/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

In a randomized, double-blind, parallel-group, placebo-controlled study in Sweden, 20 patients were randomized to receive DMSA 20 mg/kg/day in three divided doses or placebo for 14 days.²⁰ These patients experienced symptoms that were allegedly associated with amalgam fillings for at least 6 months. DMSA therapy resulted in increased urinary excretion of mercury and blood mercury levels were decreased. However, there were no statistically significant changes in any of the symptoms. The investigators concluded that although urinary excretion of mercury was increased during DMSA treatment, chelating therapy did not alleviate symptoms allegedly attributable to mercury from amalgam fillings.

Cao and colleagues reported the effects of Chemet in reducing blood mercury levels in children 12 to 33 months of age.²¹ The original study was to evaluate the use of Chemet for lead poisoning; the investigators used the blood samples for the lead study and measured the mercury levels. Blood mercury concentrations were measured one week before randomization and treatment, at one week after treatment initiation, and after three courses of treatment. Mercury was not detected/quantified in any of the blood samples. At one week of treatment, organic mercury concentration decreased 8% in the Chemet group, but remained the same in the placebo group (P = 0.04). However, the investigators suggested that the difference was not due to a reduction in the Chemet group but rather, Chemet therapy prevented a rise in the blood mercury concentration as seen in the placebo group. Chemet therapy did not reverse the accumulation of organic mercury over multiple courses over 5 months.

5. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

- POLICY:** Chelating Agents – Iron Chelators (Oral) Prior Authorization Policy
- Exjade® (deferasirox tablets for suspension – Novartis, generic)
 - Ferriprox® (deferiprone tablets and oral solution – Chiesi, generic [tablets only])
 - Jadenu® (deferasirox tablets – Novartis, generic)
 - Jadenu® Sprinkle (deferasirox oral granules – Novartis, generic)

REVIEW DATE: 01/31/2024

OVERVIEW

Oral iron chelators are indicated for the **treatment of iron overload** for specific conditions.¹⁻⁴ Exjade and Jadenu have the same chemical entity (deferasirox) in different formulations.^{1,2}

Deferasirox products (Exjade, Jadenu/Sprinkle; generics) are indicated for the following uses:^{1,2}

- **Chronic iron overload due to blood transfusions** (transfusional hemosiderosis), in patients ≥ 2 years of age.
- **Chronic iron overload in non-transfusion-dependent thalassemia syndromes**, in patients ≥ 10 years of age with a liver iron concentration of at least 5 mg of iron per gram of liver dry weight and a serum ferritin level > 300 mcg/L.

Limitations of Use: The safety and efficacy of deferasirox products when administered with other iron chelation therapy have not been established.^{1,2}

Deferiprone tablets (Ferriprox tablets, generic) are indicated for the following uses:³

- **Transfusional iron overload with thalassemia syndromes**, in patients ≥ 8 years of age.
- **Transfusional iron overload with sickle cell disease or other anemias**, in patients ≥ 8 years of age.

Ferriprox oral solution is indicated for the following uses:⁴

- **Transfusional iron overload with thalassemia syndromes**, in patients ≥ 3 years of age.
- **Transfusional iron overload with sickle cell disease or other anemias**, in patients ≥ 3 years of age.

Limitations of Use: Safety and effectiveness of deferiprone products have not been established for the treatment of transfusional iron overload in patients with myelodysplastic syndrome (MDS) or in patients with Diamond Blackfan anemia.^{3,4}

Table 1. Availability of Oral Iron Chelators.¹⁻⁴

Disease Overview

Iron chelating therapy should be considered in all patients who require long-term blood transfusions.⁵ Patients with sickle cell disease, myelodysplastic syndromes (MDS), thalassemia major, Diamond-Blackfan anemia, aplastic anemia, and other congenital and acquired forms of refractory anemia (e.g., hereditary hemochromatosis) may require regular blood transfusions and as a result, may require iron chelating therapy. This is because the body does not have an efficient mechanism to excrete iron.⁶ In patients requiring multiple blood transfusions, iron accumulates and is deposited into multiple organ systems. The long-term consequences of chronic iron overload include multiple organ dysfunction (e.g., heart, liver) and/or organ failure. Iron chelation therapy is necessary to prevent organ failure and decrease mortality.

Guidelines

- **Thalassemia Syndromes:**

- The Thalassemia International Federation published guidelines (2021) for transfusion-dependent thalassemia.⁷ Initiation of an iron chelator generally starts after 10 to 20 infusions or when serum ferritin level is > 1,000 mcg/L. Recommendations advise use based on patient characteristics and FDA-approved indications and also advocate for switching, rotating, and combining chelator regimens as needed to control iron balance or distribution.
- The American Heart Association (AHA) published a consensus statement (2013) on cardiovascular function and treatment in patients with β -thalassemia major.⁸ Deferasirox, deferiprone, and deferoxamine (injectable iron chelator) are recommended chelating treatments. The AHA advises the use of Ferriprox monotherapy in patients with cardiac siderosis, patients with reduced left ventricular ejection fraction (LVEF), or asymptomatic left ventricular dysfunction. Exjade and Jadenu monotherapy can be used in patients with detectable cardiac iron levels and normal cardiac function. However, Exjade and Jadenu are not recommended as first-choice treatment for cardiac siderosis with cardiac iron (T2*) < 6 ms or in patients with reduced LVEF.

- **MDS:** The National Comprehensive Cancer Network (NCCN) guidelines for MDS (version 3.2023 – November 10, 2023) have recommendations for the management of iron overload.⁹ NCCN advises consideration of deferasirox or deferoxamine (injectable iron chelator) to decrease iron overload (aiming for target ferritin level < 1,000 mcg/mL) in specific patients with MDS or who are potential transplant candidates. The guidelines note that deferiprone is available; however, controversy remains regarding the use of this agent for MDS due to the Boxed Warning for agranulocytosis.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of oral iron chelator products. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with oral iron chelator products as well as the monitoring required for adverse events and long-term efficacy, initial approval requires oral iron chelator products to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Documentation: Documentation is required for use of oral iron chelator products as noted in the criteria as **[documentation required]**. Documentation may include, but is not limited to, chart notes, prescription claims records, prescription receipts, and/or other information.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

01/31/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

I. Coverage of **deferasirox products** is recommended in those who meet one of the following criteria:

FDA-Approved Indications

1. **Iron Overload, Chronic – Transfusion-Related.** Approve for 1 year if the patient meets ONE of the following (A or B):

A) **Initial Therapy.** Approve if the patient meets ALL of the following (i, ii, and iii):

- i. Patient is receiving blood transfusions at regular intervals for a chronic condition; AND
Note: Examples of chronic conditions include thalassemia syndromes, myelodysplastic syndrome, chronic anemia, and sickle cell disease.
- ii. Prior to starting chelating therapy, serum ferritin level was > 1,000 mcg/L **[documentation required]**; AND
- iii. The medication is prescribed by or in consultation with a hematologist.

B) **Patient is Currently Receiving a Deferasirox Product.** Approve if the patient is benefiting from therapy, as confirmed by the prescriber.

Note: Examples of benefit from therapy include reduction in serum ferritin levels, stable disease, and reduced organ iron load.

2. **Iron Overload, Chronic – Non-Transfusion-Dependent Thalassemia Syndromes.** Approve for 1 year if the patient meets ONE of the following (A or B):

A) **Initial Therapy.** Approve if the patient meets BOTH of the following (i and ii):

- i. Prior to starting chelating therapy, serum ferritin level was > 300 mcg/L **[documentation required]**; AND
- ii. The medication is prescribed by or in consultation with a hematologist.

B) **Patient is Currently Receiving a Deferasirox Product.** Approve if the patient is benefiting from therapy, as confirmed by the prescriber.

Note: Examples of benefit from therapy include reduction in serum ferritin levels, stable disease, and reduced organ iron load.

II. Coverage of **deferiprone products** is recommended in those who meet one of the following criteria:

FDA-Approved Indications

1. **Iron Overload, Chronic – Transfusion-Related Due to Thalassemia Syndromes.** Approve for 1 year if the patient meets ONE of the following (A or B):

3. **Initial Therapy.** Approve if the patient meets BOTH of the following (i and ii):

- i. Prior to starting chelating therapy, serum ferritin level was > 1,000 mcg/L **[documentation required]**; AND
- ii. The medication is prescribed by or in consultation with a hematologist.

4. **Patient is Currently Receiving a Deferiprone Product.** Approve if the patient is benefiting from therapy, as confirmed by the prescriber.

Note: Examples of benefit from therapy include reduction in serum ferritin levels, stable disease, and reduced organ iron load.

2. **Iron Overload, Chronic – Transfusion-Related Due to Sickle Cell Disease or Other Anemias.** Approve for 1 year if the patient meets ONE of the following (A or B):

A) **Initial Therapy.** Approve if the patient meets BOTH of the following (i and ii):

- i. Prior to starting chelating therapy, serum ferritin level was > 1,000 mcg/L **[documentation required]**; AND
- ii. The medication is prescribed by or in consultation with a hematologist.

- B) Patient is Currently Receiving a Deferiprone Product.** Approve if the patient is benefiting from therapy, as confirmed by the prescriber.
Note: Examples of benefit from therapy include reduction in serum ferritin levels, stable disease, and reduced organ iron load.

Other Uses with Supportive Evidence

- 3. Iron Overload, Chronic – Non-Transfusion-Dependent Thalassemia Syndromes.** Approve for 1 year if the patient meets ONE of the following (A or B):
- A) Initial Therapy.** Approve if the patient meets BOTH of the following (i and ii):
- i.** Prior to starting chelating therapy, serum ferritin level was > 300 mcg/L **[documentation required]**; AND
 - ii.** The medication is prescribed by or in consultation with a hematologist.
- B) Patient is Currently Receiving a Deferiprone Product.** Approve if the patient is benefiting from therapy, as confirmed by the prescriber.
Note: Examples of benefit from therapy include reduction in serum ferritin levels, stable disease, and reduced organ iron load.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of oral iron chelator products is not recommended in the following situations:

- 31.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

- POLICY:** Chelating Agents – Penicillamine Products Prior Authorization with Step Therapy Policy
- Cuprimine® (penicillamine capsules – Valeant, generic)
 - Depen® (penicillamine tablets – Meda, generic)

REVIEW DATE: 12/11/2024

OVERVIEW

Penicillamine products (capsules [Cuprimine, generic] and tablets [Depen, generic]) are chelating agents indicated for the following uses:^{1,2}

- **Cystinuria.**
- **Rheumatoid arthritis**, severe, active disease in patients who have failed to respond to an adequate trial of conventional therapy.
- **Wilson's disease** (hepatolenticular degeneration).

Product labeling for Cuprimine and Depen is identical, apart from the differences in dosage forms: Cuprimine is supplied as 250 mg capsules; Depen is supplied as 250 mg tablets.^{1,2}

Guidelines

Penicillamine is discussed in the following guidelines:

- **Rheumatoid Arthritis:** Guidelines from American College of Rheumatology (2021) do not provide recommendations specifically for the use of penicillamine for rheumatoid arthritis.⁵
- **Wilson's Disease:**

The American Association for the Study of Liver Diseases (AASLD) provides guidelines for the diagnosis and management of Wilson's disease (2022).³ Diagnosis of Wilson's disease is confirmed by conducting genetic testing confirming biallelic pathogenic *ATP7B* mutations or confirmation of at least two clinical features associated with Wilson's disease (Kayser-Fleischer rings, serum ceruloplasmin levels < 20 mg/dL, liver biopsy, 24-hour urinary copper > 40 mcg/24 hours). The AASLD recommends a chelating agent (penicillamine or trientine) for initial treatment in symptomatic patients. For the treatment of presymptomatic patients or those on maintenance therapy, chelating agents and zinc are both treatment options.

The European Association for the Study of the Liver (EASL) also published a clinical practice guideline for the treatment of Wilson's disease (2012).⁴ Like the AASLD, the EASL acknowledges that numerous studies have demonstrated the effectiveness of penicillamine. A chelating agent (penicillamine or trientine) is the recommended initial treatment of symptomatic patients and a chelating agent or zinc may be used for the treatment of presymptomatic patients or patients established on maintenance therapy. In patients with neurological disease established on maintenance therapy, either a chelating agent or zinc may be used; zinc may have a role as first-line therapy in these patients. If zinc is used, careful monitoring of transaminases is needed, with changing to chelators if these laboratory parameters are increasing.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of the penicillamine products. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with penicillamine products for Wilson's disease as well as the monitoring required for adverse events and long-term efficacy, approval for this condition requires penicillamine products to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

- I. Coverage of Cuprimine and penicillamine capsules is recommended in those who meet one of the following criteria:

FDA-Approved Indications

1. **Cystinuria.** Approve for 1 year if the patient meets BOTH of the following (A and B):
 - A) According to the prescriber, patient has tried increased fluid intake; restriction of sodium and protein; and urinary alkalinization; AND
 - B) Patient meets ONE of the following (i or ii):
 - i. Generic penicillamine capsules are requested; OR
 - ii. If brand Cuprimine is prescribed, patient has tried generic penicillamine capsules AND cannot take generic penicillamine capsules due to a formulation difference in the inactive ingredient(s) [e.g., difference in dyes, fillers, preservatives] between the Brand and the bioequivalent generic product which, per the prescriber, would result in a significant allergy or serious adverse reaction.
2. **Wilson's Disease.** Approve for 1 year if the patient meets ALL of the following (A, B, C, and D):
 - A) Diagnosis of Wilson's disease is confirmed by ONE of the following (i or ii):
 - i. Genetic testing results confirming biallelic pathogenic *ATP7B* mutations (in either symptomatic or asymptomatic individuals); OR
 - ii. Confirmation of at least TWO of the following (TWO of a, b, c, or d):
 - a) Presence of Kayser-Fleischer rings; OR
 - b) Serum ceruloplasmin level < 20 mg/dL; OR
 - c) Liver biopsy findings consistent with Wilson's disease; OR
 - d) 24-hour urinary copper > 40 mcg/24 hours; AND
 - B) Patient meets ONE of the following (i, ii, iii, or iv):
 - i. Patient has tried Galzin (zinc acetate capsules); OR
 - ii. Patient has tried another zinc product (e.g., zinc sulfate, zinc gluconate, zinc acetate); OR
 - iii. According to the prescriber, patient has symptoms of Wilson's disease and zinc would not be an appropriate therapy; OR
 - iv. Patient has been started on therapy with a penicillamine product; AND
 - C) Patient meets ONE of the following (i or ii):
 - i. Generic penicillamine capsules are requested; OR
 - ii. If brand Cuprimine is prescribed, patient has tried generic penicillamine capsules AND cannot take generic penicillamine capsules due to a formulation difference in the inactive ingredient(s) [e.g., difference in dyes, fillers, preservatives] between the Brand and the bioequivalent generic product which, per the prescriber, would result in a significant allergy or serious adverse reaction; AND

D) The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, or liver transplant physician.

II. Coverage of Depen and penicillamine tablets is recommended in those who meet one of the following criteria:

FDA-Approved Indications

1. Cystinuria. Approve for 1 year if the patient meets BOTH of the following (A and B):

A) According to the prescriber, patient has tried increased fluid intake; restriction of sodium and protein; and urinary alkalinization; AND

B) Patient meets ONE of the following (i or ii):

i. **Generic penicillamine tablets are requested; OR**

ii. **If brand Depen is prescribed, patient has tried generic penicillamine tablets AND cannot take generic penicillamine tablets due to a formulation difference in the inactive ingredient(s) [e.g., difference in dyes, fillers, preservatives] between the Brand and the bioequivalent generic product which, per the prescriber, would result in a significant allergy or serious adverse reaction.**

2. Wilson's Disease. Approve for 1 year if the patient meets ALL of the following (A, B, C, and D):

A) Diagnosis of Wilson's disease is confirmed by ONE of the following (i or ii):

i. Genetic testing results confirming biallelic pathogenic *ATP7B* mutations (in either symptomatic or asymptomatic individuals); OR

ii. Confirmation of at least TWO of the following (TWO of a, b, c, or d):

a) Presence of Kayser-Fleischer rings; OR

b) Serum ceruloplasmin level < 20 mg/dL; OR

c) Liver biopsy findings consistent with Wilson's disease; OR

d) 24-hour urinary copper > 40 mcg/24 hours; AND

B) Patient meets ONE of the following (i, ii, iii, or iv):

i. Patient has tried Galzin (zinc acetate capsules); OR

ii. Patient has tried another zinc product (e.g., zinc sulfate, zinc gluconate, zinc acetate); OR

iii. According to the prescriber, patient has symptoms of Wilson's disease and zinc would not be an appropriate therapy; OR

iv. **Patient has been started on therapy with a penicillamine product; AND**

C) Patient meets ONE of the following (i or ii):

i. Generic penicillamine tablets are requested; OR

ii. **If brand Depen is prescribed, patient has tried generic penicillamine tablets AND cannot take generic penicillamine tablets due to a formulation difference in the inactive ingredient(s) [e.g., difference in dyes, fillers, preservatives] between the Brand and the bioequivalent generic product which, per the prescriber, would result in a significant allergy or serious adverse reaction; AND**

D) The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, or liver transplant physician.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of penicillamine products is not recommended in the following situations:

1. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Chelating Agents – Trientine Products Prior Authorization Policy

- Cuvrior™ (trientine tetrahydrochloride tablets – Orphalan)
- Syprine® (trientine hydrochloride capsules – Bausch, generic)

REVIEW DATE: 12/11/2024

OVERVIEW

Trientine products (capsules [Syprine, generic] and tablets [Cuvrior]) are chelating agents indicated for the treatment of **Wilson's disease** (hepatolenticular degeneration).^{1,2}

Syprine (trientine hydrochloride capsules, generic) is indicated for:¹

- Treatment of patients with **Wilson's disease** who are intolerant of penicillamine.

Cuvrior (trientine tetrahydrochloride tablets) is indicated for:²

- Treatment of adults with stable **Wilson's disease** who are de-coppered and tolerant to penicillamine.

Trientine is not indicated for use in patients with cystinuria, rheumatoid arthritis, or biliary cirrhosis.¹ Trientine products should be used when treatment with penicillamine is no longer possible because of intolerable or life-endangering side effects.¹ The content of trientine differs between products, thus they are not interchangeable on a mg per mg basis.²

Disease Overview

Wilson's disease is an autosomal recessive disorder in which alterations in cellular copper processing and impaired biliary excretion lead to copper accumulation.³⁻⁵ Copper initially builds up in the liver and is eventually released into the bloodstream and deposited into other organs (e.g., brain, kidneys, and cornea) so it can cause a wide array of symptoms. Lifelong pharmacologic therapy is the mainstay of treatment for Wilson's disease; without treatment, most patients will die from liver disease or progressive neurologic disease. Liver transplantation is reserved for severe or resistant cases. In patients with Wilson's disease, trientine acts as a general metal chelator and promotes urinary copper excretion as well as blocks dietary copper absorption.

Guidelines

The American Association for the Study of Liver Diseases (AASLD) provides guidelines for the diagnosis and management of Wilson's disease (2022).⁴ Diagnosis of Wilson's disease is confirmed by conducting genetic testing confirming biallelic pathogenic *ATP7B* mutations or confirmation of at least two clinical features associated with Wilson's disease (Kayser-Fleischer rings, serum ceruloplasmin level < 20 mg/dL, liver biopsy, 24-hour urinary copper > 40 mcg/24 hours). The AASLD recommends a chelating agent (penicillamine or trientine) for initial treatment of symptomatic patients. For the treatment of presymptomatic patients or those on maintenance therapy, chelating agents and zinc are both treatment options.

The European Association for the Study of the Liver (EASL) also published a clinical practice guideline for the treatment of Wilson's disease (2012).⁵ Like the AASLD, the EASL acknowledges that numerous studies have demonstrated the effectiveness of penicillamine. A chelating agent (penicillamine or trientine) is the recommended initial treatment of symptomatic patients, and a chelating agent or zinc may be used

for the treatment of presymptomatic patients or patients established on maintenance therapy. In patients with neurological disease established on maintenance therapy, either a chelating agent or zinc may be used; zinc may have a role as first-line therapy in these patients. If zinc is used, careful monitoring of transaminases is needed, with changing to chelators if these laboratory parameters are increasing.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of trientine products. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with trientine as well as the monitoring required for adverse events and long-term efficacy, approval requires trientine products to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of trientine is recommended in those who meet the following criteria:

FDA-Approved Indication

- 3. Wilson's Disease.** Approve for 1 year if the patient meets ALL of the following (A, B, and C):
- E) Diagnosis of Wilson's disease is confirmed by ONE of the following (i or ii):**
 - i.** Genetic testing results confirming biallelic pathogenic *ATP7B* mutations (in either symptomatic or asymptomatic individuals); OR
 - ii.** Confirmation of at least TWO of the following (TWO of a, b, c, or d):
 - a)** Presence of Kayser-Fleischer rings; OR
 - b)** Serum ceruloplasmin level < 20 mg/dL; OR
 - c)** Liver biopsy findings consistent with Wilson's disease; OR
 - d)** 24-hour urinary copper > 40 mcg/24 hours; AND
- F) Patient meets ONE of the following (i, ii, iii, iv, v or vi):**
 - i.** According to the prescriber, patient has tried one penicillamine product and is intolerant to penicillamine therapy; OR
Note: Examples of penicillamine products are Cuprimine (penicillamine capsules, generic) Depen (penicillamine tablets, generic).
 - ii.** According to the prescriber, patient has clinical features indicating the potential for intolerance to penicillamine therapy; OR
Note: Specific clinical features include of any renal disease, congestive splenomegaly causing severe thrombocytopenia, autoimmune tendency.
 - iii.** According to the prescriber, patient has a contraindication to penicillamine therapy; OR
 - iv.** Patient has neurologic manifestations of Wilson's disease; OR
 - v.** Patient is pregnant; OR
 - vi.** Patient has been started on therapy with trientine (Cuvrior or Syprine, generic).
- G) The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, or liver transplant physician.**

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of trientine products is not recommended in the following situations:

66. **Biliary Cirrhosis.** Trientine is not indicated for the treatment of biliary cirrhosis.¹
67. **Cystinuria.** Trientine is not recommended for use in patients with cystinuria.¹ Unlike penicillamine, trientine does not contain a sulfhydryl moiety and therefore it is not capable of binding cysteine.
68. **Rheumatoid Arthritis.** Trientine is not recommended for use in patients with rheumatoid arthritis.¹ Per the prescribing information, trientine was not found to be effective in improving any clinical or biochemical parameter after 12 weeks of treatment in patients with rheumatoid arthritis.
4. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

REVIEW DATE: 08/28/2024

OVERVIEW

Chenodal, a naturally occurring bile acid, is indicated for patients with **radiolucent stones** in well-opacifying gallbladders, in whom selective surgery would be undertaken except for the presence of increased surgical risk due to systemic disease or age.¹

The most widely used treatment for symptomatic gallstones is cholecystectomy.² Two naturally occurring bile acids are used in the treatment of gallstones: ursodeoxycholic acid (UrsoForte®, Urso-250®, [ursodiol tablets, generic], Actigall® [ursodiol capsules, generic]) and chenodeoxycholic acid/chenodiol (Chenodal).³ These agents reduce biliary cholesterol; however, their exact mechanisms differ. Both Chenodal and ursodiol promote the gradual dissolution of radiolucent gallstones over a period of 6 months to 2 years.²

Other Uses with Supportive Evidence

Cerebrotendinous xanthomatosis (CTX) is a lipid storage disorder with various clinical manifestations including juvenile cataracts, tendon xanthomas, premature atherosclerosis, and progressive neurologic disturbance (e.g., ataxia, seizures, psychiatric disorders, and peripheral neuropathy).⁴ Other conditions associated with CTX include osteoarthritis, skeletal fractures, pulmonary insufficiency, renal and hepatic calculi, and childhood chronic diarrhea. CTX is the result of a mutated enzyme (cytochrome P450 27-sterol hydroxylase) which is normally responsible for the conversion of cholesterol to cholic acid and chenodeoxycholic acid. In CTX, reduced synthesis of cholic and chenodeoxycholic acids results in failed feedback inhibition of cholesterol production, in turn leading to hallmark laboratory findings of the disorder: increased serum cholesterol concentrations and elevated urinary bile alcohols.⁵ Replacement therapy with chenodiol inhibits abnormal bile acid synthesis and is most effective in reducing elevated plasma cholesterol concentrations and eliminating bile alcohols.⁴

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Chenodal. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Chenodal as well as the monitoring required for adverse events and long-term efficacy, approval requires Chenodal to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Chenodal is recommended in those who meet one of the following criteria:

FDA-Approved Indication

1. **Gallstones.** Approve for 1 year if the patient meets ONE of the following (A or B):
 - A) Patient has tried an ursodiol product; OR
 - B) Patient is currently receiving an ursodiol product.

Other Uses with Supportive Evidence

2. **Cerebrotendinous Xanthomatosis.** Approve for 1 year if Chenodal is prescribed by or in consultation with a metabolic specialist who treats patients with cerebrotendinous xanthomatosis or a specialist who focuses in the treatment of cerebrotendinous xanthomatosis.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Chenodal is not recommended in the following situations:

5. **Combination Therapy with Cholbam (cholic acid capsules).** There are no efficacy data available to support use of combination therapy with Chenodal and Cholbam.
6. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Cholbam Prior Authorization Policy

- Cholbam® (cholic acid capsules – Travere)

REVIEW DATE: 07/24/2024

OVERVIEW

Cholbam, a bile acid, is indicated for the following uses:¹

- **Bile acid synthesis disorders due to single enzyme defects (SEDs).**
- **Peroxisomal disorders (PDs), including Zellweger spectrum disorders,** as adjunctive treatment in patients who exhibit manifestations of liver disease, steatorrhea, or complications from decreased fat soluble vitamin absorption.

The effects of Cholbam on extrahepatic manifestations (e.g., neurologic symptoms) of bile acid synthesis disorders due to SEDs or PDs have not been established.¹ The prescribing information states that treatment with Cholbam should be discontinued if liver function does not improve within 3 months of the start of treatment or if complete biliary obstruction develops.

Bile Acid Synthesis Disorders

Bile acids are found in the liver and have several biological roles, including promotion of bile flow and intestinal absorption of fat and fat soluble vitamins.² The two primary bile acids are cholic acid and chenodeoxycholic acid (available as Chenodal® [chenodiol tablets]). Bile acids are formed from cholesterol; inadequate bile acid production leads to accumulation of cholesterol in the body, as well as other intermediary metabolites. This can result in damage to various organ systems. Severe cases may progress to cirrhosis and liver failure. Progressive neurologic disease may also occur, even in the absence of liver disease.

There are at least 17 known enzymes involved in bile acid synthesis. Primary bile acid synthesis disorders may be caused by a defect in the gene encoding any one of these enzymes. Enrollment criteria in the pivotal studies with Cholbam were based on abnormal urinary bile acids analysis by Fast Atom Bombardment ionization – mass spectrometry (FAB-MS).¹ However, gene sequencing is now available for many of the affected enzymes.

Peroxisomal Disorders (PDs)

PDs occur due to genetic mutations to genes that are essential to the proper formation of peroxisomes.³ Among their many roles, peroxisomes are vital to the production of bile acids, as well as for neurologic function. Zellweger spectrum disorder is a type of PD and may be severe (Zellweger syndrome) or intermediate/milder (previously called neonatal adrenoleukodystrophy, infantile Refsum disease, or Heimler syndrome).⁴ Enrollment criteria in the pivotal trials were based on abnormal urinary bile acids analysis by FAB-MS and a neurologic exam.¹ However, molecular genetic testing is now available.⁴

GUIDELINES

A joint guideline by the North American and European Societies for Pediatric Gastroenterology, Hepatology, and Nutrition is available (2017).⁵ The guideline, which briefly addresses evaluation of cholestatic jaundice in infants, provides recommendations for diagnosis of bile acid synthesis disorders. While it is possible to perform rapid diagnosis of potential inborn errors in bile acid synthesis from urinary

07/24/2024

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

bile acid analysis, FAB-MS of urine is recommended. The guideline also notes that molecular techniques identify the specific mutations in genes encoding enzymes responsible for bile acid synthesis.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Cholbam. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Cholbam as well as the monitoring required for adverse events and long-term efficacy, approval requires Cholbam to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Cholbam is recommended in those who meet one of the following criteria:

FDA-Approved Indications

- 1. Bile Acid Synthesis Disorders Due to Single Enzyme Defects (SEDs).** Approve for the duration noted if the patient meets ONE of the following (A or B):
 - A) Initial Therapy.** Approve for 3 months if the patient meets BOTH of the following (i and ii):
 - i.** Patient has at least ONE of the following (a or b):
 - 1.** An abnormal urinary bile acid as confirmed by Fast Atom Bombardment ionization – Mass Spectrometry (FAB-MS) analysis; OR
 - 1.** Molecular genetic testing consistent with the diagnosis; AND
 - ii.** The medication is prescribed by or in consultation with a hepatologist, metabolic specialist, or gastroenterologist.
 - B) Patient is Currently Receiving Cholbam.** Approve for 1 year if the patient meets ALL of the following (i, ii, and iii):
 - i.** Patient has responded to initial Cholbam therapy with an improvement in liver function tests (e.g., aspartate aminotransferase [AST], alanine aminotransferase [ALT], bilirubin levels); AND
 - ii.** Patient does not have complete biliary obstruction; AND
 - iii.** The medication is prescribed by or in consultation with a hepatologist, metabolic specialist, or gastroenterologist.
- 2. Bile Acid Synthesis Disorders Due to Peroxisomal Disorders (PDs), Including Zellweger Spectrum Disorders.** Approve for the duration noted if the patient meets ONE of the following (A or B):
 - A) Initial Therapy.** Approve for 3 months if the patient meets ALL of the following (i, ii, and iii):
 - i.** Patient has peroxisomal disorders with at least ONE of the following (a or b):
 - 1.** An abnormal urinary bile acid analysis by Fast Atom Bombardment ionization – Mass Spectrometry (FAB-MS); OR
 - 1.** Molecular genetic testing consistent with the diagnosis; AND
 - ii.** Patient has liver disease, steatorrhea, or complications from decreased fat soluble vitamin absorption (e.g., rickets); AND
 - iii.** The medication is prescribed by or in consultation with a hepatologist, metabolic specialist, or gastroenterologist.

07/24/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- B) Patient is Currently Receiving Cholbam.** Approve for 1 year if the patient meets ALL of the following (i, ii, and iii):
- i.** Patient has responded to initial Cholbam therapy according to the prescriber; AND
Note: Examples of a response to initial Cholbam therapy include improvements in liver enzymes or improvement in steatorrhea.
 - ii.** Patient does not have complete biliary obstruction; AND
 - iii.** The medication is prescribed by or in consultation with a hepatologist, metabolic specialist, or gastroenterologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Cholbam is not recommended in the following situations:

- 69. Concomitant Use with Chenodal.** There are no efficacy data available to support concomitant use of Cholbam and Chenodal.
- 70.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Cinacalcet Prior Authorization Policy

- Sensipar® (cinacalcet tablets – Amgen, generic)

REVIEW DATE: 03/27/2024

Overview

Cinacalcet, a calcium-sensing receptor agonist (calcimimetic), is indicated for the following uses:¹

- **Hypercalcemia parathyroid carcinoma** in adults.
- **Hypercalcemia with primary hyperparathyroidism** in adults for whom parathyroidectomy would be indicated on the basis of serum calcium levels, but who are unable to undergo parathyroidectomy.
- **Secondary hyperparathyroidism** with chronic kidney disease (CKD) in adults on dialysis.

Limitation of use: Cinacalcet is not indicated for use in patients with CKD who are not on dialysis due to increased risk of hypocalcemia.

Disease Overview

Secondary hyperparathyroidism is a frequent complication of CKD caused by a reduction in circulating calcitriol levels and disturbances in calcium and phosphorous metabolism.² This leads to increases in the parathyroid hormone (PTH) levels, which then leads to osteoclastic activity resulting in bone resorption and marrow fibrosis.

Parathyroid carcinoma, a rare malignant cancer, is an uncommon cause of primary hyperparathyroidism.³ The condition is associated with higher serum calcium and PTH levels than primary hyperparathyroidism due to benign adenoma. The primary cause of morbidity in patients with parathyroid carcinoma is due to complications of hypercalcemia (e.g., cardiac arrhythmias, renal failure). Surgical resection of the malignancy may relieve symptoms and reduce serum calcium levels. Medical therapy with cinacalcet and intravenous bisphosphonates are useful adjunct therapies to control hypercalcemia.

Guidelines

The Kidney Disease: Improving Global Outcomes (KDIGO) clinical practice guidelines (2009; updated 2017) for the treatment of CKD-mineral bone disorder (CKD-MBD) consider calcimimetics (cinacalcet), calcitriol, or vitamin D analogs (or a combination of these agents) as reasonable first-line options for patients with CKD stage 5D who require PTH-lowering therapy.^{4,5} If intact parathyroid hormone (iPTH) levels fall below two times the upper limit of normal for the assay, these products should be reduced or discontinued

Other Uses with Supportive Evidence

The KDIGO clinical practice guidelines (2017) for the treatment of CKD-MBD note that although cinacalcet is not approved for the treatment of hyperparathyroidism in kidney transplant recipients, it is used in these patients, especially those with significant hypercalcemia.^{4,5}

03/27/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of cinacalcet. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with cinacalcet as well as the monitoring required for adverse events and long-term efficacy, approval requires cinacalcet to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: When available, the ICD-9/ICD-10 codes for Malignant Neoplasm of Parathyroid Gland (ICD-9: 194.1* and ICD-10: C75.0*) AND “oncologist or endocrinologist” will be used as part of automation to allow approval of the requested medication.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of cinacalcet is recommended in those who meet one of the following criteria:

FDA-Approved Indications

3. **Hypercalcemia due to Parathyroid Carcinoma.** Approve for 1 year if cinacalcet is prescribed by or in consultation with an oncologist or endocrinologist.
4. **Hypercalcemia in a Patient with Primary Hyperparathyroidism.** Approve for 1 year if the patient meets BOTH of the following (A and B):
 - A) Patient has failed or is unable to undergo a parathyroidectomy due to a contraindication; AND
 - B) The medication is prescribed by or in consultation with a nephrologist or endocrinologist.
5. **Secondary Hyperparathyroidism.** Approve for 1 year if the patient meets ALL of the following (A, B, C, and D):
 - A) Patient has chronic kidney disease; AND
 - B) Patient is on dialysis; AND
 - C) The baseline (prior to starting cinacalcet therapy) intact parathyroid hormone (iPTH) level is at least two times the upper limit of normal as defined by the laboratory reference value measured on two separate occasions; AND
 - D) The medication is prescribed by or in consultation with a nephrologist or endocrinologist.

Other Uses with Supportive Evidence

6. **Hyperparathyroidism in a Post-Renal Transplant Patient.** Approve for 1 year if the patient meets BOTH of the following (A and B):
 - A) The baseline (prior to starting cinacalcet therapy) calcium and intact parathyroid hormone (iPTH) levels are above the normal range, as defined by the laboratory reference values; AND
 - B) The medication is prescribed by or in consultation with a transplant physician, nephrologist, or endocrinologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of cinacalcet is not recommended in the following situations:

71. **Patient with Primary Hyperparathyroidism Eligible for Parathyroidectomy.** Parathyroidectomy is the primary treatment for primary hyperparathyroidism.

PRIOR AUTHORIZATION POLICY

- POLICY:** Colony Stimulating Factors – Filgrastim Products Prior Authorization Policy
- Neupogen® (filgrastim intravenous or subcutaneous injection – Amgen)
 - Nivestym® (filgrastim-aafi intravenous or subcutaneous injection – Hospira/Pfizer)
 - Nypozi™ (filgrastim-txid intravenous or subcutaneous injection – Tanvex)
 - Releuko® (filgrastim-ayow intravenous or subcutaneous injection – Amneal)
 - Zarxio® (filgrastim-sndz intravenous or subcutaneous injection – Sandoz)

REVIEW DATE: 10/09/2024; selected revision 12/04/2024

OVERVIEW

Filgrastim, a granulocyte colony stimulating factor (G-CSF), is indicated for the following uses:¹⁻⁵

- **Decrease the incidence of infection as manifested by febrile neutropenia**, in patients with nonmyeloid malignancies receiving myelosuppressive anti-cancer drugs associated with a significant incidence of severe neutropenia with fever.
- **Mobilization of hematopoietic progenitor cells**, into the peripheral blood for collection by leukapheresis.
- **Reduce the time to neutrophil recovery and the duration of fever**, following induction or consolidation chemotherapy treatment of adults with acute myeloid leukemia (AML).
- **Reduce the duration of neutropenia and neutropenia-related clinical sequelae (e.g., febrile neutropenia)**, in patients with nonmyeloid malignancies undergoing myeloablative chemotherapy followed by bone marrow transplantation (BMT).
- **Reduce the incidence and duration of sequelae of neutropenia (e.g., fever, infections, oropharyngeal ulcers)**, in symptomatic patients with congenital neutropenia, cyclic neutropenia, or idiopathic neutropenia
- **Increase survival in patients acutely exposed to myelosuppressive doses of radiation** (Hematopoietic Syndrome of Acute Radiation Syndrome [H-ARS])

Nivestym, Nypozi, Releuko, and Zarxio are biosimilars to Neupogen.¹⁻⁵ Releuko indication labeling does not include mobilization of autologous hematopoietic progenitor cells into the peripheral blood for collection by leukapheresis.⁴ Neupogen, Nypozi, and Zarxio labeling include the indication for treatment of H-ARS.^{1,2,5}

Guidelines

The National Comprehensive Cancer Network (NCCN) addresses the use of filgrastim products in several guidelines. Of note, throughout the recommendations, it is acknowledged that an FDA-approved biosimilar is an appropriate substitute for filgrastim.

- **Acute Lymphoblastic Leukemia (ALL):** Guidelines (version 2.2024 – July 19, 2024) recommend granulocyte colony stimulating factors (CSFs) as supportive care for myelosuppressive blocks of therapy or as directed by treatment protocol.⁶
- **Acute Myeloid Leukemia (AML):** Guidelines (version 3.2024 – May 17, 2024) recommend granulocyte colony stimulating factors (CSFs) as supportive care for myelosuppressive blocks of therapy or as directed by treatment protocol.²³
- **Hematopoietic Cell Transplantation:** Guidelines (version 2.2024 – August 30, 2024) recommend filgrastim for hematopoietic cell mobilization for allogeneic or autologous donors as a single agent or in combination with other treatments.⁷

10/09/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- **Hematopoietic Growth Factors:** Guidelines (version 3.2024 – January 30, 2024) recommend filgrastim, along with other CSFs, for prophylactic use if the patient is receiving anti-cancer medications that are associated with a high (> 20%) incidence of severe neutropenia with fever.⁸ Consider CSF therapy for patients with an intermediate (10% to 20%) probability of developing febrile neutropenia based on risk factors. The NCCN guidelines also recommend therapy with CSFs in other scenarios in those given myelosuppressive chemotherapy.
- **Management of Immunotherapy-Related Toxicities:** Guidelines (version 1.2024 – December 7, 2023) recommend granulocyte CSFs as supportive care for neutropenic patients with Grade 1 cytokine release syndrome resulting from chimeric antigen receptor T-cell therapy.⁹
- **Myelodysplastic Syndromes (MDS):** Guidelines (version 3.2024 – July 25, 2024) consider filgrastim for use in certain patients (e.g., neutropenic patients with recurrent or resistant infections, combination use with epoetin alfa or Aranesp® [darbepoetin alfa injection] in patients with anemia).¹⁰

The American Society of Clinical Oncology clinical practice guidelines for the use of white blood cell growth factors (2015) recommend CSFs to reduce the risk of febrile neutropenia in patients receiving cancer chemotherapy.¹¹ CSFs may be considered in patients receiving radiation therapy alone if prolonged delays secondary to neutropenia are expected. The guidelines state CSFs should be avoided in patients receiving concomitant chemotherapy and radiation therapy, particularly involving the mediastinum.

Other Uses with Supportive Evidence

Neutropenia occurs in patients with human immunodeficiency virus (HIV) and may be caused by medications or due to the disease process. Studies have demonstrated positive outcomes with the use of filgrastim for the treatment of neutropenia in this patient population.¹²⁻¹⁵

Filgrastim has been used for agranulocytosis caused by non-cytotoxic medications, primarily described in case series, case reports and literature reviews.¹⁶⁻²²

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of filgrastim products. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with filgrastim products as well as the monitoring required for adverse events and long-term efficacy, approval for some conditions requires filgrastim products to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of filgrastim products is recommended in those who meet one of the following:

FDA-Approved Indications

1. **Acute Myeloid Leukemia (AML) in a Patient Receiving Chemotherapy.** Approve for 6 months if prescribed by or in consultation with an oncologist or hematologist.

2. **Bone Marrow Transplant (BMT) in a Patient with Cancer Who Received Chemotherapy.** Approve for 1 month if prescribed by or in consultation with a hematologist, an oncologist, or a physician who specializes in transplantation.
3. **Cancer in a Patient Receiving Myelosuppressive Chemotherapy.** Approve for 6 months if the patient meets BOTH of the following (A and B):
- A) Patient meets ONE of the following (i, ii, iii, or iv):
- i. Patient is receiving myelosuppressive anti-cancer medications that are associated with a high risk of febrile neutropenia (the risk is at least 20% based on the chemotherapy regimen); OR
 - ii. Patient meets BOTH of the following (a and b):
 - a) Patient is receiving myelosuppressive anti-cancer medications that are associated with a risk of febrile neutropenia, but the risk is less than 20% based on the chemotherapy regimen; AND
 - b) Patient has at least one risk factor for febrile neutropenia according to the prescriber; OR
Note: Examples of risk factors include age > 65 years of age receiving full chemotherapy dose intensity; prior chemotherapy or radiation therapy; persistent neutropenia; bone marrow involvement by tumor; recent surgery and/or open wounds; liver dysfunction (bilirubin > 2.0 mg/dL); renal dysfunction (creatinine clearance < 50 mL/min); poor performance status; patients with human immunodeficiency virus (HIV) infection and low CD4 counts.
 - iii. Patient meets BOTH of the following (a and b):
 - a) Patient has had a neutropenic complication from a prior chemotherapy cycle and did not receive prophylaxis with a colony stimulating factor; AND
Note: Examples of colony stimulating factors include filgrastim products, pegfilgrastim products, Ryzneuta (efbemalenograstim alfa-vuxw subcutaneous injection), Rolvedon (eflapograstim-xnst subcutaneous injection).
 - b) A reduced dose or frequency of chemotherapy may compromise treatment outcome; OR
 - iv. Patient who has received chemotherapy has febrile neutropenia and has at least one risk factor for poor clinical outcomes or for developing infection-associated complications according to the prescriber; AND
Note: Examples of risk factors include sepsis syndrome; age > 65 years; severe neutropenia (absolute neutrophil count [ANC] < 100 cells/mm³); neutropenia expected to be > 10 days in duration; pneumonia or other clinically documented infections; invasive fungal infection; hospitalization at the time of fever; prior episode of febrile neutropenia.
- B) The medication is prescribed by or in consultation with an oncologist or hematologist.
4. **Peripheral Blood Progenitor Cell (PBPC) Collection and Therapy.** Approve for 1 month if prescribed by or in consultation with an oncologist, a hematologist, or a physician who specializes in transplantation.
5. **Radiation Syndrome (Hematopoietic Syndrome of Acute Radiation Syndrome [H-ARS]).** Approve for 1 month if prescribed by or in consultation with a physician who has expertise in treating acute radiation syndrome.
6. **Severe Chronic Neutropenia (e.g., Congenital Neutropenia, Cyclic Neutropenia, Idiopathic Neutropenia).** Approve for 6 months if prescribed by or in consultation with a hematologist.

Other Uses with Supportive Evidence

10/09/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

7. **Acute Lymphoblastic Leukemia (ALL) in a Patient Receiving Chemotherapy.** Approve for 1 month if prescribed by or in consultation with an oncologist or a hematologist.
8. **Cytokine Release Syndrome associated with Chimeric Antigen Receptor (CAR) T-Cell Therapy.** Approve for 1 month if prescribed for a patient who has neutropenia.
Note: Examples of CAR T-cell therapy include Abecma (idecabtagene vicleucel), Breyanzi (lisocabtagene maraleucel), Carvykti (ciltacabtagene autoleucel), Kymriah (tisagenlecleucel), Tecartus (brexucabtagene autoleucel) and Yescarta (axicabtagene ciloleucel).
9. **Drug-Induced (Non-Chemotherapy) Agranulocytosis or Neutropenia.** Approve for 1 month.
10. **Myelodysplastic Syndromes (MDS).** Approve for 3 months if prescribed by or in consultation with an oncologist or hematologist.
11. **Neutropenia Associated with Human Immunodeficiency Virus (HIV) or Acquired Immunodeficiency Syndrome (AIDS).** Approve for 4 months if the agent is prescribed by or in consultation with a physician who specializes in infectious diseases, a hematologist, or a physician who specializes in the management of HIV/AIDS.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of filgrastim products is not recommended in the following situations:

7. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Colony Stimulating Factors – Granix Prior Authorization Policy

- Granix® (tbo-filgrastim subcutaneous injection – Teva)

REVIEW DATE: 10/09/2024

OVERVIEW

Granix, a granulocyte colony stimulating factor (G-CSF), is indicated to reduce the duration of severe neutropenia in adults and pediatric patients ≥ 1 month of age with non-myeloid malignancies receiving myelosuppressive anti-cancer medications associated with a clinically significant incidence of febrile neutropenia.¹

Guidelines

The National Comprehensive Cancer Network (NCCN) addresses the use of Granix in guidelines. Of note, throughout the recommendations, it is acknowledged that Granix is an appropriate substitute for filgrastim.

- **Hematopoietic Cell Transplantation:** Guidelines (version 2.2024 – August 30, 2024) recommend filgrastim for hematopoietic cell mobilization for allogeneic or autologous donors as a single agent or in combination with other treatments.⁴
- **Hematopoietic Growth Factors:** Guidelines (version 3.2024 – January 30, 2024) recommend Granix, along with other granulocyte colony stimulating factors (CSFs), for prophylactic use if the patient is receiving anti-cancer medications that are associated with a high ($> 20\%$) incidence of severe neutropenia with fever.² Consider CSF therapy for patients with an intermediate (10% to 20%) probability of developing febrile neutropenia based on risk factors. The NCCN guidelines also recommend therapy with CSFs in other scenarios in those given myelosuppressive chemotherapy. Granix is also recommended as an appropriate option for the treatment of patients with radiation-induced myelosuppression following a radiologic/nuclear incident (Hematopoietic Syndrome of Acute Radiation Syndrome [H-ARS]).
- **Myelodysplastic Syndromes (MDS):** Guidelines (version 3.2024 – July 25, 2024) recommend Granix for use in certain patients with MDS (e.g., neutropenic patients with recurrent or resistant infections, combination use with epoetin alfa or Aranesp® [darbepoetin alfa injection] in patients with anemia).³

The American Society of Clinical Oncology clinical practice guidelines for the use of white blood cell growth factors (2015) recommends CSFs to reduce the risk of febrile neutropenia in patients receiving cancer chemotherapy.⁵ CSFs may be considered in patients receiving radiation therapy alone if prolonged delays secondary to neutropenia are expected. The guidelines state CSFs should be avoided in patients receiving concomitant chemotherapy and radiation therapy, particularly involving the mediastinum.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Granix. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Granix as well as the monitoring required for adverse events and long-term efficacy, approval requires Granix to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Granix is recommended in those who meet one of the following criteria:

FDA-Approved Indication

12. Cancer in a Patient Receiving Myelosuppressive Chemotherapy. Approve for 6 months if the patient meets BOTH of the following (A and B):

B) Patient meets ONE of the following (i, ii, iii, or iv):

- i. Patient is receiving myelosuppressive anti-cancer medications that are associated with a high risk of febrile neutropenia (the risk is at least 20% based on the chemotherapy regimen); OR
- ii. Patient meets BOTH of the following (a and b):
 - a. Patient is receiving myelosuppressive anti-cancer medications that are associated with a risk of febrile neutropenia, but the risk is less than 20% based on the chemotherapy regimen; AND
 - b. Patient has at least one risk factor for febrile neutropenia according to the prescriber; OR
Note: Examples of risk factors include age > 65 year receiving full chemotherapy dose intensity; prior chemotherapy or radiation therapy; persistent neutropenia; bone marrow involvement by tumor; recent surgery and/or open wounds; liver dysfunction (bilirubin > 2.0 mg/dL); renal dysfunction (creatinine clearance < 50 mL/min); poor performance status; human immunodeficiency virus (HIV) infection patients with low CD4 counts.
- iii. Patient meets BOTH of the following (a and b):
 - a. Patient has had a neutropenic complication from a prior chemotherapy cycle and did not receive prophylaxis with a colony stimulating factor; AND
Note: Examples of colony stimulating factors include filgrastim products, pegfilgrastim products, Ryzneuta (efbemalenograftim alfa-vuxw subcutaneous injection), Rolvedon (eflapograftim-xnst subcutaneous injection).
 - b. A reduced dose or frequency of chemotherapy may compromise treatment outcome; OR
- iv. Patient who has received chemotherapy has febrile neutropenia AND has at least one risk factor for poor clinical outcomes or for developing infection-associated complications according to the prescriber; AND

Note: Examples of risk factors include sepsis syndrome; age > 65 years; severe neutropenia (absolute neutrophil count [ANC] < 100 cells/mm³); neutropenia expected to be > 10 days in duration; pneumonia or other clinically documented infections; invasive fungal infection; hospitalization at the time of fever; prior episode of febrile neutropenia.

B) The medication is prescribed by or in consultation with an oncologist or hematologist.

Other Uses with Supportive Evidence

13. Myelodysplastic Syndromes (MDS). Approve for 3 months if prescribed by or in consultation with an oncologist or hematologist.

14. Peripheral Blood Progenitor Cell (PBPC) Collection and Therapy. Approve for 1 month if prescribed by or in consultation with an oncologist, a hematologist, or a physician who specializes in transplantation.

15. Radiation Syndrome (Hematopoietic Syndrome of Acute Radiation Syndrome [H-ARS]).

Approve for 1 month if prescribed by or in consultation with a physician who has expertise in treating acute radiation syndrome.

PRIOR AUTHORIZATION POLICY

POLICY: Colony Stimulating Factors – Leukine Prior Authorization Policy

- Leukine® (sargramostim intravenous or subcutaneous injection – Partner Therapeutics)

REVIEW DATE: 10/09/2024

OVERVIEW

Leukine, a granulocyte-macrophage colony stimulating factor (GM-CSF), is indicated for the following uses:¹

- **Acute exposure to myelosuppressive doses of radiation**, to increase survival in adult and pediatric patients from birth to 17 years of age acutely exposed to myelosuppressive doses of radiation (Hematopoietic Syndrome of Acute Radiation Syndrome [H-ARS]).
- **Acute myeloid leukemia (AML) following induction chemotherapy**, to shorten the time to neutrophil recovery and to reduce the incidence of severe, life-threatening, or fatal infections in patients ≥ 55 years of age.
- **Allogeneic bone marrow transplantation**, for acceleration of myeloid reconstitution in patients ≥ 2 years of age undergoing allogeneic bone marrow transplantation from human leukocyte antigen (HLA)-matched related donors.
- **Allogeneic or autologous bone marrow transplantation: treatment of delayed neutrophil recovery or graft failure**, treatment of patients ≥ 2 years of age who have undergone allogeneic or autologous bone marrow transplantation in whom neutrophil recovery is delayed or failed.
- **Autologous peripheral blood progenitor cell mobilization and collection**, in adult patients with cancer undergoing autologous hematopoietic stem cell transplantation for the mobilization of hematopoietic progenitor cells into peripheral blood for collection by leukapheresis.
- **Autologous peripheral blood progenitor cell (PBPC) and bone marrow transplantation (BMT)**, for acceleration of myeloid reconstitution after autologous PBPC or bone marrow transplantation in patients ≥ 2 years of age with non-Hodgkin's lymphoma, acute lymphoblastic leukemia (ALL), and Hodgkin's lymphoma.

Other Uses with Supportive Evidence

Unituxin® (dinutuximab intravenous infusion) is indicated for use in combination with GM-CSF, interleukin-2, and 13-cis-retinoic acid for the treatment of pediatric patients with high-risk neuroblastoma who achieve at least a partial response to first-line multiagent, multimodality therapy.² Danyelza® (naxitamab-gqgk intravenous infusion) is indicated for use in combination with GM-CSF, for the treatment of patients 1 year of age and older with relapsed or refractory high-risk neuroblastoma in the bone or bone marrow who have demonstrated a partial response, minor response, or stable disease to prior therapy.³

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Leukine. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Leukine as well as the monitoring required for adverse events and long-term efficacy, approval requires Leukine to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Leukine is recommended in those who meet one of the following criteria:

FDA-Approved Indications

- 30. Acute Myeloid Leukemia (AML) in a Patient Receiving Chemotherapy.** Approve for 6 months if the medication is prescribed by or in consultation with an oncologist or a hematologist.
- 31. Bone Marrow Transplant (BMT).** Approve for 1 month if the medication is prescribed by or in consultation with a hematologist, an oncologist, or a physician who specializes in transplantation.
- 32. Peripheral Blood Progenitor Cell (PBPC) Collection and Therapy.** Approve for up to 14 days if the medication is prescribed by or in consultation with an oncologist, a hematologist, or a physician that specializes in transplantation.
- 33. Radiation Syndrome (Hematopoietic Syndrome of Acute Radiation Syndrome [H-ARS]).** Approve for 1 month if the medication is prescribed by or in consultation with a physician with expertise in treating acute radiation syndrome.

Other Uses with Supportive Evidence

- 34. Neuroblastoma.** Approve for 6 months if the patient meets BOTH of the following (A and B):
 - A)** Patient is requesting Leukine in a regimen that recommends administration in combination with a granulocyte-macrophage colony stimulating factor (GM-CSF); AND
Note: Examples of medications that are administered in combination with a GM-CSF include Unituxin (dinutuximab intravenous infusion), Danyelza (naxitamab intravenous infusion).
 - B)** The medication is prescribed by or in consultation with an oncologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Leukine is not recommended in the following situations:

- 9.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Colony Stimulating Factors – Pegfilgrastim Products Prior Authorization Policy

- Neulasta® (pegfilgrastim subcutaneous injection – Amgen)
- Fulphila™ (pegfilgrastim-jmdb subcutaneous injection – Mylan)
- Fylnetra® (pegfilgrastim-pbbk subcutaneous injection – Kashiv)
- Nyvepria™ (pegfilgrastim-apgf subcutaneous injection – Pfizer)
- Stimufend® (pegfilgrastim-fpgk subcutaneous injection – Fresenius Kabi)
- Udenyca® (pegfilgrastim-cbqv subcutaneous injection – Coherus)
- Ziextenzo™ (pegfilgrastim-bmez subcutaneous injection – Sandoz)

REVIEW DATE: 10/09/2024

OVERVIEW

Pegfilgrastim, a granulocyte colony stimulating factor (G-CSF), is indicated for the following uses:¹⁻⁷

- **Decrease the incidence of infection, as manifested by febrile neutropenia**, in patients with non-myeloid malignancies receiving myelosuppressive anti-cancer drugs associated with a clinically significant incidence of febrile neutropenia
- **Increase survival in patients acutely exposed to myelosuppressive doses of radiation** (Hematopoietic Syndrome of Acute Radiation Syndrome [H-ARS])

Fulphila, Fylnetra, Nyvepria, Stimufend, Udenyca, and Ziextenzo are biosimilars to Neulasta.¹⁻⁷ Only Neulasta, Stimufend, Udenyca, and Ziextenzo labeling carries the indication for treatment of H-ARS.^{1,3,4,7}

Guidelines

The National Comprehensive Cancer Network (NCCN) addresses the use of pegfilgrastim products in several guidelines. Of note, throughout the recommendations, it is acknowledged that an FDA-approved biosimilar is an appropriate substitute for pegfilgrastim.^{8,9}

- **Hematopoietic Cell Transplantation:** Guidelines (version 2.2024 – August 30, 2024) recommend pegfilgrastim for hematopoietic cell mobilization for autologous donors as a single agent or in combination with other treatments.⁸
- **Hematopoietic Growth Factors:** Guidelines (version 3.2024 – January 30, 2024) recommend pegfilgrastim, along with other colony stimulating factors (CSFs), for prophylactic use if the patient is receiving anti-cancer medications that are associated with a high (> 20%) incidence of severe neutropenia with fever.⁹ Consider CSF therapy for patients with an intermediate (10% to 20%) probability of developing febrile neutropenia based on risk factors. The NCCN guidelines also recommend therapy with CSFs in other scenarios in those given myelosuppressive chemotherapy. Of note, pegfilgrastim, Rolvedon, and Ryzneuta have only been studied for prophylactic use, not for treatment of febrile neutropenia.

The American Society of Clinical Oncology clinical practice guidelines for the use of white blood cell growth factors (2015) recommends CSFs to reduce the risk of febrile neutropenia in patients receiving cancer chemotherapy.⁸ CSFs may be considered in patients receiving radiation therapy alone if prolonged delays secondary to neutropenia are expected. The guidelines state CSFs should be avoided in patients receiving concomitant chemotherapy and radiation therapy, particularly involving the mediastinum.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of pegfilgrastim products is recommended in those who meet one of the following criteria:

FDA-Approved Indications

16. Cancer in a Patient Receiving Myelosuppressive Chemotherapy. Approve for 6 months if the patient meets BOTH of the following (A and B):

A) Patient meets ONE of the following (i, ii, or iii):

i. Patient is receiving myelosuppressive anti-cancer medications that are associated with a high risk of febrile neutropenia (the risk is at least 20% based on the chemotherapy regimen); OR

ii. Patient meets BOTH of the following (a and b):

a) Patient is receiving myelosuppressive anti-cancer medications that are associated with a risk of febrile neutropenia, but the risk is less than 20% based on the chemotherapy regimen; AND

b) Patient has at least one risk factor for febrile neutropenia according to the prescriber; OR
Note: Examples of risk factors include age > 65 year receiving full chemotherapy dose intensity; prior chemotherapy or radiation therapy; persistent neutropenia; bone marrow involvement by tumor; recent surgery and/or open wounds; liver dysfunction (bilirubin > 2.0 mg/dL); renal dysfunction (creatinine clearance < 50 mL/min); poor performance status; human immunodeficiency virus (HIV) infection patients with low CD4 counts.

iii. Patient meets BOTH of the following (a and b):

a) Patient has had a neutropenic complication from a prior chemotherapy cycle and did not receive prophylaxis with a colony stimulating factor; AND

Note: Examples of colony stimulating factors include filgrastim products, pegfilgrastim products, Ryzneuta (efbemalenograftim alfa-vuxw subcutaneous injection), Rolvedon (eflapegrastim-xnst subcutaneous injection).

b) A reduced dose or frequency of chemotherapy may compromise treatment outcome; AND

B) The medication is prescribed by or in consultation with an oncologist or hematologist.

2. Radiation Syndrome (Hematopoietic Syndrome of Acute Radiation Syndrome [H-ARS]).

Approve for 1 month if the agent is prescribed by or in consultation with a physician who has expertise in treating acute radiation syndrome.

Other Uses with Supportive Evidence

3. Peripheral Blood Progenitor Cell (PBPC) Collection and Therapy. Approve one dose if prescribed by or in consultation with an oncologist, a hematologist, or a physician who specializes in transplantation.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

PRIOR AUTHORIZATION POLICY

POLICY: Colony Stimulating Factors – Rolvedon Prior Authorization Policy

- Rolvedon® (eflapegrastim-xnst subcutaneous injection – Spectrum)

REVIEW DATE: 10/09/2024

OVERVIEW

Rolvedon, a granulocyte colony stimulating factor (G-CSF), is indicated to **decrease the incidence of infection, as manifested by febrile neutropenia**, in adults with non-myeloid malignancies receiving myelosuppressive anti-cancer drugs associated with a clinically significant incidence of febrile neutropenia.¹

Limitation of use: Rolvedon is not indicated for the mobilization of peripheral blood progenitor cells (PBPCs) for hematopoietic stem cell transplantation.¹

Safety and effectiveness in pediatric patients have not been established.¹

Guidelines

The National Comprehensive Cancer Network (NCCN) guidelines for **hematopoietic growth factors** (version 3.2024 – January 30, 2024) recommend Rolvedon, along with other CSFs, for prophylactic use if the patient is receiving anti-cancer medications that are associated with a high (> 20%) incidence of severe neutropenia with fever.² Consider CSF therapy for patients with an intermediate (10% to 20%) probability of developing febrile neutropenia based on risk factors. The NCCN guidelines also recommend therapy with CSFs in other scenarios in those given myelosuppressive chemotherapy. Of note, pegfilgrastim Rolvedon, and Ryzneuta® (efbemalenogristim alfa-vuxw subcutaneous injection) have only been studied for prophylactic use, not for treatment of febrile neutropenia.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Rolvedon. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Rolvedon as well as the monitoring required for adverse events and long-term efficacy, approval requires Rolvedon to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Rolvedon is recommended in those who meet the following criteria:

FDA-Approved Indication

17. Cancer in a Patient Receiving Myelosuppressive Chemotherapy. Approve for 6 months if the patient meets ALL of the following (A, B, and C):

B) Patient is ≥ 18 years of age; AND

10/09/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- C) Patient meets ONE of the following (i, ii, or iii):
- v. Patient is receiving myelosuppressive anti-cancer medications that are associated with a high risk of febrile neutropenia (the risk is at least 20% based on the chemotherapy regimen); OR
 - vi. Patient meets BOTH of the following (a and b):
 - a) Patient is receiving myelosuppressive anti-cancer medications that are associated with a risk of febrile neutropenia, but the risk is less than 20% based on the chemotherapy regimen; AND
 - b) Patient has at least one risk factor for febrile neutropenia according to the prescriber; OR
Note: Examples of risk factors include age > 65 year receiving full chemotherapy dose intensity; prior chemotherapy or radiation therapy; persistent neutropenia; bone marrow involvement by tumor; recent surgery and/or open wounds; liver dysfunction (bilirubin > 2.0 mg/dL); renal dysfunction (creatinine clearance < 50 mL/min); poor performance status; human immunodeficiency virus (HIV) infection patients with low CD4 counts.
 - vii. Patient meets BOTH of the following (a and b):
 - a) Patient has had a neutropenic complication from a prior chemotherapy cycle and did not receive prophylaxis with a colony stimulating factor; AND
Note: Examples of colony stimulating factors include filgrastim products, pegfilgrastim products, Ryzneuta (efbemalenogristim alfa-vuxw subcutaneous injection).
 - b) A reduced dose or frequency of chemotherapy may compromise treatment outcome; AND
- D) The medication is prescribed by or in consultation with an oncologist or hematologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Rolvedon is not recommended in the following situations:

- 12. Peripheral Blood Progenitor Cell (PBPC) Collection and Therapy.** As a limitation of use in the Rolvedon prescribing information, it is noted that Rolvedon is not indicated for the mobilization of peripheral blood progenitor cells for hematopoietic stem cell transplantation.¹
- 13.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Colony Stimulating Factors – Ryzneuta Prior Authorization Policy

- Ryzneuta® (efbemalenograstim alfa-vuxw subcutaneous injection – Evive)

REVIEW DATE: 10/09/2024

OVERVIEW

Ryzneuta, a granulocyte colony stimulating factor (G-CSF), is indicated to **decrease the incidence of infection, as manifested by febrile neutropenia**, in adults with non-myeloid malignancies receiving myelosuppressive anti-cancer drugs associated with a clinically significant incidence of febrile neutropenia.¹

Limitation of use: Ryzneuta is not indicated for the mobilization of peripheral blood progenitor cells (PBPCs) for hematopoietic stem cell transplantation.¹

Safety and effectiveness in pediatric patients have not been established.¹

Guidelines

The National Comprehensive Cancer Network (NCCN) guidelines for **hematopoietic growth factors** (version 3.2024 – January 30, 2024) recommend Ryzneuta, along with other CSFs, for prophylactic use if the patient is receiving anti-cancer medications that are associated with a high (> 20%) incidence of severe neutropenia with fever.² Consider CSF therapy for patients with an intermediate (10% to 20%) probability of developing febrile neutropenia based on risk factors. The NCCN guidelines also recommend therapy with CSFs in other scenarios in those given myelosuppressive chemotherapy. Of note, pegfilgrastim Rolvedon® (eflapgrastim-xnst subcutaneous injection), and Ryzneuta have only been studied for prophylactic use, not for treatment of febrile neutropenia.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Ryzneuta. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Ryzneuta as well as the monitoring required for adverse events and long-term efficacy, approval requires Ryzneuta to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Ryzneuta is recommended in those who meet the following criteria:

FDA-Approved Indication

- 18. Cancer in a Patient Receiving Myelosuppressive Chemotherapy.** Approve for 6 months if the patient meets ALL of the following (A, B, and C):
- E) Patient is ≥ 18 years of age; AND

10/09/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- F)** Patient meets ONE of the following (i, ii, or iii):
- viii.** Patient is receiving myelosuppressive anti-cancer medications that are associated with a high risk of febrile neutropenia (the risk is at least 20% based on the chemotherapy regimen); OR
 - ix.** Patient meets BOTH of the following (a and b):
 - a)** Patient is receiving myelosuppressive anti-cancer medications that are associated with a risk of febrile neutropenia, but the risk is less than 20% based on the chemotherapy regimen; AND
 - b)** Patient has at least ONE risk factor for febrile neutropenia according to the prescriber; OR
Note: Examples of risk factors include age > 65 year receiving full chemotherapy dose intensity; prior chemotherapy or radiation therapy; persistent neutropenia; bone marrow involvement by tumor; recent surgery and/or open wounds; liver dysfunction (bilirubin > 2.0 mg/dL); renal dysfunction (creatinine clearance < 50 mL/min); poor performance status; human immunodeficiency virus (HIV) infection patients with low CD4 counts.
 - x.** Patient meets BOTH of the following (a and b):
 - a)** Patient has had a neutropenic complication from prior chemotherapy cycle and did not receive prophylaxis with a colony stimulating factor; AND
Note: Examples of colony stimulating factors include filgrastim products, pegfilgrastim products, Rolvedon (eflapregastim-xnst subcutaneous injection)..
 - b)** A reduced dose or frequency of chemotherapy may compromise treatment outcome; AND
- G)** The medication is prescribed by or in consultation with an oncologist or hematologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Ryzneuta is not recommended in the following situations:

- 14. Peripheral Blood Progenitor Cell (PBPC) Collection and Therapy.** As a limitation of use in the Ryzneuta prescribing information, it is noted that Ryzneuta is not indicated for the mobilization of peripheral blood progenitor cells for hematopoietic stem cell transplantation.¹
- 15.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Complement Inhibitors – Empaveli Prior Authorization Policy

- Empaveli™ (pegcetacoplan subcutaneous injection – Apellis)

REVIEW DATE: 05/29/2024

OVERVIEW

Empaveli, a complement C3 inhibitor, is indicated for the treatment of **paroxysmal nocturnal hemoglobinuria** (PNH) in adults.¹ Empaveli is given subcutaneously, via an infusion pump or an on-body injector.

Empaveli has a Boxed Warning regarding serious infections caused by encapsulated bacteria. Empaveli is only available through a restricted access program, Empaveli Risk Evaluation and Mitigation Strategy (REMS).

Disease Overview

Paroxysmal nocturnal hemoglobinuria (PNH) is a rare, genetic disorder of hematopoietic stem cells.^{2,3} The mutation in the X-linked gene phosphatidylinositol glycan class A (PIGA) results in a deficiency in the glycosylphosphatidylinositol (GPI) protein, which is responsible for anchoring other protein moieties to the surface of the erythrocytes. Loss of anchoring of these proteins causes cells to hemolyze and leads to complications such as hemolytic anemia, thrombosis, and peripheral blood cytopenias. PNH is a clinical diagnosis that should be confirmed with peripheral blood flow cytometry to detect the absence or severe deficiency of GPI-anchored proteins on at least two lineages.^{2,4} Prior to the availability of complement inhibitors, only supportive measures in terms of managing the cytopenias and controlling thrombotic risk were available. Supportive measures include platelet transfusion, immunosuppressive therapy for patients with bone marrow failure, use of erythropoietin for anemias, and aggressive anticoagulation.

Dosing Recommendations When Switching to Empaveli from Soliris® (eculizumab intravenous infusion)

For patients switching from Soliris® (eculizumab intravenous [IV] infusion) to Empaveli, initiate Empaveli while continuing Soliris at the current dose.¹ After 4 weeks, discontinue Soliris and continue Empaveli monotherapy. For patients switching from Ultomiris® (ravulizumab-cwzy IV infusion or subcutaneous injection), initiate Empaveli no more than 4 weeks after the last dose of Ultomiris. There is no information regarding dosing recommendations for patients switching from Fabhalta® (iptacopan capsule) to Empaveli.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Empaveli. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Empaveli as well as the monitoring required for adverse events and long-term efficacy, approval requires Empaveli to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

05/29/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Coverage of Empaveli is recommended in those who meet the following criteria:

FDA-Approved Indication

7. **Paroxysmal Nocturnal Hemoglobinuria.** Approve for the duration noted if the patient meets ONE of the following (A or B):
- A) **Initial therapy.** Approve for 6 months if the patient meets ALL of the following (i, ii, iii, and iv):
- i. Patient is ≥ 18 years of age; AND
 - ii. Paroxysmal nocturnal hemoglobinuria diagnosis was confirmed by peripheral blood flow cytometry results showing the absence or deficiency of glycosylphosphatidylinositol-anchored proteins on at least two cell lineages; AND
 - iii. For a patient transitioning to Empaveli from Soliris (eculizumab intravenous infusion), the prescriber attests that Soliris will be discontinued 4 weeks after starting Empaveli; AND
 - iv. The medication is prescribed by or in consultation with a hematologist.
- B) **Patient is Currently Receiving Empaveli.** Approve for 1 year if the patient meets ALL of the following (i, ii, and iii):
- i. Patient is ≥ 18 years of age; AND
 - ii. Patient is continuing to derive benefit from Empaveli according to the prescriber; AND
Note: Examples of benefit include increase in or stabilization of hemoglobin levels, decreased transfusion requirements or transfusion independence, reductions in hemolysis, improvement in Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue score.
 - iii. The medication is prescribed by or in consultation with a hematologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Empaveli is not recommended in the following situations:

16. **Concomitant Use with Soliris (eculizumab intravenous infusion) for > 4 weeks.** There is no evidence to support concomitant use of Empaveli with Soliris. However, to reduce the risk of hemolysis from abrupt treatment discontinuation in a patient switching from Soliris to Empaveli, the patient should be initiated on Empaveli while continuing Soliris. After 4 weeks, discontinue Soliris and continue Empaveli monotherapy.
17. **Concomitant Use with Fabhalta (iptacopan capsule), Ultomiris (ravulizumab-cwvz intravenous infusion or subcutaneous injection), or Voydeya (danicopan tablets).** There is no evidence to support concomitant use of Empaveli with Fabhalta, Ultomiris, or Voydeya.
18. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Complement Inhibitors – Fabhalta Prior Authorization Policy

- Fabhalta® (iptacopan capsules – Novartis)

REVIEW DATE: 12/11/2024

OVERVIEW

Fabhalta, a Factor B inhibitor, is indicated for the following uses:¹

- **Paroxysmal nocturnal hemoglobinuria (PNH)**, treatment in adults.
- **Primary immunoglobulin A nephropathy (IgAN)**, for the reduction of proteinuria in adults at risk of rapid disease progression, generally a urine protein-to-creatinine ratio (UPCR) ≥ 1.5 g/g.

Fabhalta has a Boxed Warning about serious meningococcal infections.¹ Fabhalta is only available through a restricted access program, Fabhalta Risk Evaluation and Mitigation Strategy (REMS).

Disease Overview

PNH

PNH is a rare, genetic disorder of hematopoietic stem cells.^{2,3} The mutation in the X-linked gene phosphatidylinositol glycan class A (PIGA) results in a deficiency in the glycosylphosphatidylinositol (GPI) protein, which is responsible for anchoring other protein moieties to the surface of the erythrocytes. Loss of anchoring of these proteins causes cells to hemolyze and leads to complications such as hemolytic anemia, thrombosis, and peripheral blood cytopenias. PNH is a clinical diagnosis that should be confirmed with peripheral blood flow cytometry to detect the absence or severe deficiency of GPI-anchored proteins on at least two lineages.^{2,5} Prior to the availability of complement inhibitors, only supportive management, in terms of managing the cytopenias and controlling thrombotic risk were available. Supportive measures include platelet transfusion, immunosuppressive therapy for patients with bone marrow failure, use of erythropoietin for anemias, and aggressive anticoagulation.

IgAN

IgAN is the most common primary glomerular disease in the world and it is the leading cause of CKD and kidney failure.⁵ The disease is slowly progressive; approximately 25% to 30% of patients develop kidney failure within 20 to 25 years of presentation. The management of IgAN is focused on supportive care to slow the rate of disease progression. IgAN is characterized by a single histopathologic criterion of predominant or co-dominant IgA deposits on kidney biopsy, however, it is well recognized that the disease exhibits heterogeneity in clinical and pathological features. Hypertension and proteinuria are major risk factors for the progression of CKD. Guidelines from Kidney Diseases: Improving Global Outcomes (KDIGO) note that proteinuria reduction to < 0.5 g/day, a surrogate marker of improved kidney outcomes in IgAN, is a reasonable target.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Fabhalta. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Fabhalta as well as the monitoring required for adverse events and long-term efficacy, approval requires Fabhalta to be prescribed by or in consultation with a physician who specializes in the condition being treated.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Fabhalta is recommended in those who meet one of the following criteria:

FDA-Approved Indication

1. **Paroxysmal Nocturnal Hemoglobinuria.** Approve for the duration noted if the patient meets ONE of the following (A or B):
 - C) **Initial therapy.** Approve for 6 months if the patient meets ALL of the following (i, ii, and iii):
 - v. Patient is ≥ 18 years of age; AND
 - vi. Paroxysmal nocturnal hemoglobinuria diagnosis was confirmed by peripheral blood flow cytometry results showing the absence or deficiency of glycosylphosphatidylinositol-anchored proteins on at least two cell lineages; AND
 - vii. The medication is prescribed by or in consultation with a hematologist.
 - D) **Patient is Currently Receiving Fabhalta.** Approve for 1 year if the patient meets ALL of the following (i, ii, and iii):
 - iv. Patient is ≥ 18 years of age; AND
 - v. According to the prescriber, patient is continuing to derive benefit from Fabhalta; AND
Note: Examples of benefit include increase in or stabilization of hemoglobin levels, decreased transfusion requirements or transfusion independence, reductions in hemolysis, improvement in Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue score.
 - vi. The medication is prescribed by or in consultation with a hematologist.
2. **Primary Immunoglobulin A Nephropathy.** Approve for the duration noted if the patient meets ONE of the following (A or B):
3. **Initial Therapy.** Approve for 9 months if the patient meets ALL of the following (i, ii, iii, iv, v, and vi):
 4. Patient is ≥ 18 years of age; AND
 5. The diagnosis has been confirmed by biopsy; AND
 6. Patient is at high risk of disease progression, defined by meeting BOTH of the following (a and b):
 7. Patient meets ONE of the following [(1) or (2)]:
 8. Proteinuria ≥ 0.5 g/day; OR
 9. Urine protein-to-creatinine ratio ≥ 1.5 g/g; AND
 10. Patient has received the maximum or maximally tolerated dose of ONE of the following for ≥ 12 weeks prior to starting Fabhalta [(1) or (2)]:
 11. Angiotensin converting enzyme inhibitor; OR
 12. Angiotensin receptor blocker; AND
 13. Patient has received ≥ 3 months of optimized supportive care, including blood pressure management, lifestyle modification, and cardiovascular risk modification, according to the prescriber; AND
 14. Patient has an estimated glomerular filtration rate ≥ 30 mL/min/1.73 m²; AND
 15. The medication is prescribed by or on consultation with a nephrologist.
- B) **Patient is Currently Receiving Fabhalta.** Approve for 1 year if the patient meets ALL of the following (i, ii, iii, iv, and v):
 - i. Patient is ≥ 18 years of age; AND
 - ii. The diagnosis has been confirmed by biopsy; AND

- iii. According to the prescriber, patient has had a response to Fabhalta; AND
Note: Examples of a response are a reduction in urine protein-to-creatinine ratio from baseline, reduction in proteinuria from baseline.
- iv. Patient has an estimated glomerular filtration rate ≥ 30 mL/min/1.73 m²; AND
- v. The medication is prescribed by or on consultation with a nephrologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Fabhalta is not recommended in the following situations:

1. **Concomitant Use with Another Complement Inhibitor.** There is no evidence to support concomitant use of Fabhalta with another complement inhibitor.
Note: Examples of complement inhibitors are Empaveli (pegcetacoplan subcutaneous injection), PiaSky (crovalimab-akkz intravenous infusion or subcutaneous injection), eculizumab intravenous infusion (Soliris, biosimilars), Ultomiris (ravulizumab-cwzy intravenous infusion), and Voydeya (danicopan tablets).
2. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Complement Inhibitors – PiaSky Prior Authorization Policy

- PiaSky® (c30alimab-akkz intravenous infusion or subcutaneous injection – Genentech/Roche)

REVIEW DATE: 07/10/2024

OVERVIEW

PiaSky, a complement C5 inhibitor, is indicated for the treatment of **paroxysmal nocturnal hemoglobinuria** (PNH) in patients ≥ 13 years of age who weigh ≥ 40 kg.¹

Disease Overview

Paroxysmal nocturnal hemoglobinuria (PNH) is a rare, genetic disorder of hematopoietic stem cells.^{2,3} The mutation in the X-linked gene phosphatidylinositol glycan class A (PIGA) results in a deficiency in the glycosylphosphatidylinositol (GPI) protein, which is responsible for anchoring other protein moieties to the surface of the erythrocytes. Loss of anchoring of these proteins causes cells to hemolyze and leads to complications such as hemolytic anemia, thrombosis, and peripheral blood cytopenias. PNH is a clinical diagnosis that should be confirmed with peripheral blood flow cytometry to detect the absence or severe deficiency of GPI-anchored proteins on at least two lineages.^{2,5} Prior to the availability of complement inhibitors, only supportive management, in terms of managing the cytopenias and controlling thrombotic risk were available. Supportive measures include platelet transfusion, immunosuppressive therapy for patients with bone marrow failure, use of erythropoietin for anemias, and aggressive anticoagulation.

Dosing Information

The recommended dosage regimen for PiaSky consists of one loading dose administered by intravenous infusion on Day 1, followed by four weekly loading doses administered by subcutaneous (SC) injection on Days 2, 8, 15, and 22.¹ Maintenance doses, which are given once every 4 weeks by SC injection, start on Day 29. Only healthcare providers should administer PiaSky.

Safety

The PiaSky prescribing information has a Boxed Warning about serious meningococcal infections.¹ PiaSky is only available through a restricted access program, PiaSky Risk Evaluation and Mitigation Strategy (REMS).

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of PiaSky intravenous. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with PiaSky intravenous as well as the monitoring required for adverse events and long-term efficacy, approval requires PiaSky intravenous to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of PiaSky is recommended in those who meet the following criteria:

FDA-Approved Indication

- 16. Paroxysmal Nocturnal Hemoglobinuria.** Approve for the duration noted if the patient meets ONE of the following (A or B):
- E) Initial therapy.** Approve for 6 months if the patient meets ALL of the following (i, ii, iii, and iv):
- viii.** Patient is ≥ 13 years of age; AND
 - ix.** Patient weighs ≥ 40 kg; AND
 - x.** Diagnosis was confirmed by peripheral blood flow cytometry results showing the absence or deficiency of glycosylphosphatidylinositol (GPI)-anchored proteins on at least two cell lineages; AND
 - xi.** The medication is prescribed by or in consultation with a hematologist.
- B) Patient is Currently Receiving PiaSky subcutaneous.** Approve for 1 year if the patient meets ALL of the following (i, ii, iii, and iv):
- Note: A patient who has not started maintenance therapy with PiaSky subcutaneous should be considered under criterion A (Initial Therapy).
- i.** Patient is ≥ 13 years of age; AND
 - ii.** Patient weighs ≥ 40 kg; AND
 - iii.** According to the prescriber, patient is continuing to derive benefit from PiaSky; AND
- Note: Examples of benefit include increase in or stabilization of hemoglobin levels, decreased transfusion requirements or transfusion independence, reductions in hemolysis.
- iv.** The medication is prescribed by or in consultation with a hematologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of PiaSky is not recommended in the following situations:

- 2. Concomitant Use with Another Complement Inhibitor.** There is no evidence to support concomitant use of PiaSky with another complement inhibitor.
- Note: Examples of complement inhibitors are Empaveli (pegcetacoplan subcutaneous injection), Fabhalta (iptacopan capsule), Soliris (eculizumab intravenous infusion), Ultomiris (ravulizumab cwzy intravenous infusion or subcutaneous injection), Voydeya (danicopan tablets).
- 3.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Complement Inhibitors – Soliris Prior Authorization Policy

- Soliris® (eculizumab intravenous infusion – Alexion)

REVIEW DATE: 09/25/2024

OVERVIEW

Soliris, a complement C5 inhibitor, is indicated for the following uses:¹

- **Atypical hemolytic uremic syndrome (aHUS)**, to inhibit complement-mediated thrombotic microangiopathy.
Limitation of Use. Soliris is not indicated for the treatment of patients with Shiga toxin *Escherichia coli*-related hemolytic uremic syndrome.
- **Generalized myasthenia gravis (gMG)**, in adults who are anti-acetylcholine receptor (AChR) antibody-positive.
- **Neuromyelitis optica spectrum disorder (NMOSD)**, in adults who are anti-aquaporin-4 (AQP4) antibody-positive.
- **Paroxysmal nocturnal hemoglobinuria (PNH)**, to reduce hemolysis.

The Soliris prescribing information has a Boxed Warning about serious meningococcal infections.¹ Soliris is only available through a restricted access program, Ultomiris and Soliris Risk Evaluation and Mitigation Strategy (REMS).

The safety and effectiveness of Soliris for the treatment of PNH, gMG, and NMOSD in pediatric patients have not been established.¹ The safety and effectiveness of Soliris in pediatric patients for aHUS is supported by evidence from four adequate and well-controlled clinical studies assessing the safety and effectiveness of Soliris for the treatment of aHUS.

Disease Overview

Hemolytic uremic syndrome (HUS) is defined as the triad of non-immune hemolytic anemia, thrombocytopenia, and acute renal failure, in which the underlying lesions are mediated by systemic thrombotic microangiopathy.² aHUS should be distinguished from a more common condition referred to as typical HUS.³ aHUS is a sub-type of HUS in which thrombotic microangiopathy is the consequence of endothelial damage in the microvasculature of the kidneys and other organs due to a dysregulation of the activity of the complement system. The typical form is caused by infection with certain strains of *E. coli* bacteria that produce toxic substances called Shiga-like toxins; Soliris is not indicated for the treatment of Shiga toxin *E. coli*-related hemolytic uremic syndrome.¹⁻³

Myasthenia gravis (MG) is a chronic autoimmune neuromuscular disease that causes weakness in the skeletal muscles, which are responsible for breathing and moving parts of the body, including the arms and legs.⁴ The hallmark of MG is muscle weakness that worsens after periods of activity and improves after periods of rest. Acquired MG results from the binding of autoantibodies to components of the neuromuscular junction, most commonly the AChR.⁵ Soliris was studied in patients with gMG with anti-AChR antibodies with a Myasthenia Gravis Foundation of America (MGFA) clinical classification class II to IV and a Myasthenia Gravis-Activities of Daily Living (MG-ADL) total score ≥ 6 .¹

NMOSD is a rare, relapsing, autoimmune disorder of the brain and spinal cord with optic neuritis and/or myelitis as predominate characteristic symptoms.⁶ NMOSD often causes significant, permanent damage

09/25/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

to vision and/or spinal cord function resulting in blindness or impaired mobility.⁷ Patients may experience pain, paralysis, loss of bowel and bladder control, loss of visual acuity, uncontrolled motor functions, and complications can cause death.

PNH is a rare, genetic disorder of hematopoietic stem cells.^{8,9} The mutation in the X-linked gene phosphatidylinositol glycan class A (PIGA) results in a deficiency in the glycosylphosphatidylinositol (GPI) protein, which is responsible for anchoring other protein moieties to the surface of the erythrocytes. Loss of anchoring of these proteins causes cells to hemolyze and leads to complications such as hemolytic anemia, thrombosis, and peripheral blood cytopenias. PNH is a clinical diagnosis that should be confirmed with peripheral blood flow cytometry to detect the absence or severe deficiency of GPI-anchored proteins on at least two cell lineages.^{8,10} Prior to the availability of complement inhibitors, only supportive measures, in terms of managing the cytopenias and controlling thrombotic risk, were available. Supportive measures include platelet transfusion, immunosuppressive therapy for patients with bone marrow failure, use of erythropoietin for anemias, and aggressive anticoagulation.

Recommendations

There are no formal guidelines for treatment of aHUS.

A consensus statement for the diagnosis and treatment of PNH was published in 2021.⁸ Treatment options for PNH are supportive care, allogeneic hematopoietic stem cell transplantation, and complement blockade by the anti-C5 monoclonal antibody (Soliris). Supportive care include use of oral iron to replace the large urinary losses; folate and vitamin B₁₂ supplementation; red blood cell transfusion when these measures do not maintain adequate hemoglobin levels; use of antibiotics to treat bacterial infections as soon as possible since infections can exacerbate hemolytic crises in patients with PNH; use of corticosteroids to reduce the severity and duration of the hemolytic crises; use of Soliris as primary prophylaxis in patients with high PNH clone size (granulocyte close > 50%), high level of D dimer, pregnancy, perioperative condition, and other associated thrombophilia risk factors; and use of immunosuppressives in patients with PNH and aplastic anemia and bone marrow deficiency.

An international consensus guidance for the management of MG was published in 2016.⁵ The consensus guidance recommends pyridostigmine for the initial treatment in most patients with MG. The ability to discontinue pyridostigmine can indicate that the patient has met treatment goals and may guide the tapering of other therapies. Corticosteroids or immunosuppressant therapy should be used in all patients with MG who have not met treatment goals after an adequate trial of pyridostigmine. Nonsteroidal immunosuppressant agents used in MG include azathioprine, cyclosporine, mycophenolate mofetil, methotrexate, and tacrolimus. It is usually necessary to maintain some immunosuppression for many years, sometimes for life. Plasma exchange and intravenous immunoglobulin can be used as short-term treatments in certain patients. A 2020 update to this consensus guidance provides new recommendations for methotrexate, rituximab, and Soliris.¹¹ All recommendations should be considered extensions or additions to recommendations made in the initial international consensus guidance. Oral methotrexate may be considered as a steroid-sparing agent in patients with gMG who have not tolerated or responded to steroid-sparing agents. Rituximab should be considered as an early therapeutic option in patients with anti-muscle specific kinase antibody-positive MG who have an unsatisfactory response to initial immunotherapy. Soliris should be considered in the treatment of severe, refractory, anti-AChR antibody-positive MG.

The Neuromyelitis Optica Study Group (NEMOS) published revised recommendations for the treatment of NMOSD in 2024.¹² The standard of care for the treatment of NMOSD attacks (for both AQP4-IgG-positive and double-negative cases) are high-dose glucocorticoids and/or apheresis therapy. Long term immunotherapy is recommended for patients with AQP4-IgG-positive NMOSD. NEMOS notes the first-choice therapies for the treatment of AQP4-IgG-positive NMOSD are Soliris, Ultomiris® (ravulizumab-cwyz intravenous infusion), Enspryng® (satralizumab-mwge subcutaneous injection), Uplizna® (inebilizumab-cdon intravenous infusion), and rituximab. The order of preference for these therapies is unclear and further comparative trials and real-world data are needed. The choice of treatment is dependent on several factors, including disease activity and severity, mode and onset of action, possibility to combine it with immunosuppressive drugs, effect on autoimmune and other comorbidities, gender (family planning issues), frequency and route of administration, side effect profile, as well as patient and physician preference. In general, if a patient fails a first-choice treatment, another first-choice treatment should be tried; other options include use of a second-choice treatment (azathioprine, mycophenolate mofetil, low-dose oral glucocorticoids) or the addition of a second-choice treatment to the regimen.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Soliris. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Soliris as well as the monitoring required for adverse events and long-term efficacy, approval requires Soliris to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Soliris is recommended in those who meet one of the following criteria:

FDA-Approved Indications

- 17. Atypical Hemolytic Uremic Syndrome.** Approve for 1 year if the patient meets BOTH of the following (A and B):
 5. Patient does not have Shiga toxin *Escherichia coli*-related hemolytic uremic syndrome; AND
 6. The medication is prescribed by or in consultation with a nephrologist.
- 18. Generalized Myasthenia Gravis.** Approve for the duration noted if the patient meets ONE of the following (A or B):
 - B) Initial therapy.** Approve for 6 months if the patient meets ALL of the following (i, ii, iii, iv, v, vi, and vii):
 - i. Patient is ≥ 18 years of age; AND
 - ii. Patient has confirmed anti-acetylcholine receptor antibody-positive generalized myasthenia gravis; AND
 - iii. Patient meets BOTH of the following (a and b):
 - a) Myasthenia Gravis Foundation of America classification of II to IV; AND
 - b) Myasthenia Gravis Activities of Daily Living (MG-ADL) score of ≥ 6 ; AND
 - iv. Patient meets ONE of the following (a or b):
 - a) Patient previously received or is currently receiving pyridostigmine; OR
 - b) Patient has had inadequate efficacy, a contraindication, or significant intolerance to pyridostigmine; AND
 - v. Patient meets ONE of the following (a or b):

09/25/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- a) Patient previously received or is currently receiving two different immunosuppressant therapies for ≥ 1 year; OR
 - b) Patient had inadequate efficacy, a contraindication, or significant intolerance to two different immunosuppressant therapies; AND
Note: Examples of immunosuppressant therapies tried include azathioprine, cyclosporine, mycophenolate mofetil, methotrexate, tacrolimus, and cyclophosphamide.
 - vi. Patient has evidence of unresolved symptoms of generalized myasthenia gravis; AND
Note: Evidence of unresolved symptoms of generalized myasthenia gravis includes difficulty swallowing, difficulty breathing, and a functional disability resulting in the discontinuation of physical activity (e.g., double vision, talking, impairment of mobility).
 - vii. The medication is prescribed by or in consultation with a neurologist.
 - C) Patient is Currently Receiving Soliris. Approve for 1 year if the patient meets ALL of the following (i, ii, and iii):
 - i. Patient is ≥ 18 years of age; AND
 - ii. According to the prescriber, patient is continuing to derive benefit from Soliris; AND
Note: Examples of benefit include reductions in exacerbations of myasthenia gravis; improvements in speech, swallowing, mobility, and respiratory function.
 - iii. The medication is prescribed by or in consultation with a neurologist.
- 19. Neuromyelitis Optica Spectrum Disorder.** Approve for the duration noted if the patient meets ONE of the following (A or B):
- A) Initial Therapy. Approve for 1 year if the patient meets ALL of the following (i, ii, and iii):
 - i. Patient is ≥ 18 years of age; AND
 - ii. Diagnosis was confirmed by a positive blood serum test for anti-aquaporin-4 antibody; AND
 - iii. The medication is prescribed by or in consultation with a neurologist.
 - B) Patient is Currently Receiving Soliris. Approve for 1 year if the patient meets ALL of the following criteria (i, ii, iii, and iv):
 - i. Patient is ≥ 18 years of age; AND
 - ii. Diagnosis was confirmed by a positive blood serum test for anti-aquaporin-4 antibody; AND
 - iii. According to the prescriber, patient has had clinical benefit from the use of Soliris; AND
Note: Examples of clinical benefit include reduction in relapse rate, reduction in symptoms (e.g., pain, fatigue, motor function), and a slowing progression in symptoms.
 - iv. The medication is prescribed by or in consultation with a neurologist.
- 20. Paroxysmal Nocturnal Hemoglobinuria.** Approve for the duration noted if the patient meets ONE of the following (A or B):
- F) Initial therapy. Approve for 6 months if the patient meets ALL of the following (i, ii, and iii):
 - v. Patient is ≥ 18 years of age; AND
 - vi. Diagnosis was confirmed by peripheral blood flow cytometry results showing the absence or deficiency of glycosylphosphatidylinositol (GPI)-anchored proteins on at least two cell lineages; AND
 - vii. The medication is prescribed by or in consultation with a hematologist.
 - C) Patient is Currently Receiving Soliris. Approve for 1 year if the patient meets ALL of the following (i, ii, and iii):
 - i. Patient is ≥ 18 years of age; AND
 - ii. According to the prescriber, patient is continuing to derive benefit from Soliris; AND
Note: Examples of benefit include stabilization of hemoglobin levels, decreased transfusion requirements or transfusion independence, reductions in hemolysis, improvement in Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue score.
 - iii. The medication is prescribed by or in consultation with a hematologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Soliris is not recommended in the following situations:

4. **Concomitant Use with Empaveli > 4 Weeks.** Concomitant use of Soliris with Empaveli is not recommended. However, to reduce the risk of hemolysis from abrupt treatment discontinuation in a patient switching from Soliris to Empaveli, patient should use both therapies for 4 weeks; after which, Soliris is discontinued and patient is continued on Empaveli monotherapy.
5. **Concomitant Use with Another Complement Inhibitor Except Voydeya (danicopan tablets).** There is no evidence to support concomitant use of Soliris with another complement inhibitor, except Voydeya.
Note: Examples of complement inhibitors are Fabhalta (iptacopan capsules), PiaSky (crovalimab-akkz intravenous infusion or subcutaneous injection), and Ultomiris (ravulizumab-cwzy intravenous infusion).
6. **Concomitant Use with a Rituximab Product, a Neonatal Fc Receptor Blocker, or Zilbrysq (zilucoplan subcutaneous injection).** There is no evidence to support concomitant use of Soliris with a rituximab product, a neonatal Fc receptor blocker, or Zilbrysq.
Note: Examples of Neonatal Fc receptor blockers are Rystiggo (rozanolixizumab-noli subcutaneous infusion), Vyvgart (efgartigimod alfa-fcab intravenous infusion), and Vyvgart Hytrulo (efgartigimod alfa and hyaluronidase-qvfc subcutaneous injection).
7. **Concomitant Use with Enspryng (satralizumab-mwge subcutaneous injection) or Uplizna (inebilizumab-cdon intravenous infusion).** There is no evidence to support concomitant use of Soliris with Enspryng or Uplizna.
8. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Complement Inhibitors – Ultomiris Prior Authorization Policy

- Ultomiris® (ravulizumab-cwvz intravenous infusion – Alexion)

REVIEW DATE: 09/25/2024

OVERVIEW

Ultomiris, a complement inhibitor, is indicated for the following uses:¹

- **Atypical hemolytic uremic syndrome (aHUS)**, to inhibit complement-mediated thrombotic microangiopathy in patients ≥ 1 month of age.
Limitation of use: Ultomiris is not indicated for the treatment of patients with Shiga toxin *Escherichia coli*-related hemolytic uremic syndrome.
- **Generalized myasthenia gravis (gMG)**, in adults who are anti-acetylcholine receptor (AChR) antibody-positive.
- **Neuromyelitis Optica Spectrum Disorder (NMOSD)**, in adults who are anti-aquaporin-4 (AQP4) antibody-positive.
- **Paroxysmal nocturnal hemoglobinuria (PNH)**, in patients ≥ 1 month of age.

Ultomiris has a Boxed Warning about serious meningococcal infections.¹ Ultomiris is only available through a restricted access program, Ultomiris and Soliris Risk Evaluation and Mitigation Strategy (REMS).

Disease Overview

Hemolytic uremic syndrome (HUS) is defined as the triad of non-immune hemolytic anemia, thrombocytopenia, and acute renal failure, in which the underlying lesions are mediated by systemic thrombotic microangiopathy.² aHUS should be distinguished from a more common condition referred to as typical HUS.³ aHUS is a sub-type of HUS in which thrombotic microangiopathy is the consequence of endothelial damage in the microvasculature of the kidneys and other organs due to a dysregulation of the activity of the complement system. The typical form is caused by infection with certain strains of *E. coli* bacteria that produce toxic substances called Shiga-like toxins; Ultomiris is not indicated for the treatment of Shiga toxin *E. coli*-related hemolytic uremic syndrome.^{1,3}

Myasthenia gravis (MG) is a chronic autoimmune neuromuscular disease that causes weakness in the skeletal muscles, which are responsible for breathing and moving parts of the body, including the arms and legs.⁴ The hallmark of MG is muscle weakness that worsens after periods of activity and improves after periods of rest. Acquired MG results from the binding of autoantibodies to components of the neuromuscular junction, most commonly the AChR.⁵ Ultomiris was studied in patients with gMG with anti-AChR antibodies with a Myasthenia Gravis Foundation of America (MGFA) clinical classification class II to IV, and a Myasthenia Gravis-Activities of Daily Living (MG-ADL) total score ≥ 6 .¹

NMOSD is a rare, relapsing, autoimmune disorder of the brain and spinal cord with optic neuritis and/or myelitis as predominate characteristic symptoms.⁶ NMOSD often causes significant, permanent damage to vision and/or spinal cord function resulting in blindness or impaired mobility.⁷ Patients may experience pain, paralysis, loss of bowel and bladder control, loss of visual acuity, uncontrolled motor functions, and complications can cause death.

Paroxysmal nocturnal hemoglobinuria (PNH) is a rare, genetic disorder of hematopoietic stem cells.^{8,9} The mutation in the X-linked gene phosphatidylinositol glycan class A (PIGA) results in a deficiency in the

09/25/2024

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

glycosylphosphatidylinositol (GPI) protein, which is responsible for anchoring other protein moieties to the surface of the erythrocytes. Loss of anchoring of these proteins causes cells to hemolyze and leads to complications such as hemolytic anemia, thrombosis, and peripheral blood cytopenias. PNH is a clinical diagnosis that should be confirmed with peripheral blood flow cytometry to detect the absence or severe deficiency of GPI-anchored proteins on at least two lineages.^{8,10} Prior to the availability of complement inhibitors, only supportive measures in terms of managing the cytopenias and controlling thrombotic risk were available. Supportive measures include platelet transfusion, immunosuppressive therapy for patients with bone marrow failure, use of erythropoietin for anemias, and aggressive anticoagulation.

Recommendations

There are no formal guidelines for treatment of aHUS.

An international consensus guidance for the management of MG was published in 2016.⁵ The consensus guidance recommends pyridostigmine for the initial treatment in most patients with MG. The ability to discontinue pyridostigmine can indicate that the patient has met treatment goals and may guide the tapering of other therapies. Corticosteroids or immunosuppressant therapy should be used in all patients with MG who have not met treatment goals after an adequate trial of pyridostigmine. Nonsteroidal immunosuppressant agents used in MG include azathioprine, cyclosporine, mycophenolate mofetil, methotrexate, and tacrolimus. It is usually necessary to maintain some immunosuppression for many years, sometimes for life. Plasma exchange and intravenous immunoglobulin can be used as short-term treatments in certain patients. A 2020 update to these guidelines provides new recommendations for methotrexate, rituximab, and Soliris® (eculizumab intravenous infusion).⁹ All recommendations should be considered extensions or additions to recommendations made in the initial international consensus guidance. Oral methotrexate may be considered as a steroid-sparing agent in patients with gMG who have not tolerated or responded to steroid-sparing agents. Rituximab should be considered as an early therapeutic option in patients with anti-muscle specific kinase antibody-positive MG who have an unsatisfactory response to initial immunotherapy. Soliris should be considered in the treatment of severe, refractory, anti-AChR antibody-positive gMG.

The Neuromyelitis Optica Study Group (NEMOS) published revised recommendations for the treatment of NMOSD in 2024.¹² The standard of care for the treatment of NMOSD attacks (for both AQP4-IgG-positive and double-negative cases) are high-dose glucocorticoids and/or apheresis therapy. Long term immunotherapy is recommended for patients with AQP4-IgG-positive NMOSD. NEMOS notes the first-choice therapies for the treatment of AQP4-IgG-positive NMOSD are Enspryng® (satralizumab-mwge subcutaneous injection), Soliris, Ultomiris, Uplizna® (inebilizumab-cdon intravenous infusion), and rituximab. The order of preference for these therapies is unclear and further comparative trials and real-world data are needed. The choice of treatment is dependent on several factors, including disease activity and severity, mode and onset of action, possibility to combine it with immunosuppressive drugs, effect on autoimmune and other comorbidities, gender (family planning issues), frequency and route of administration, side effect profile, as well as patient and physician preference. In general, if a patient fails a first-choice treatment, another first-choice treatment should be tried; other options include use of a second-choice treatment (azathioprine, mycophenolate mofetil, low-dose oral glucocorticoids) or the addition of a second-choice treatment to the regimen.

A consensus statement for the diagnosis and treatment of PNH was published in 2021.⁸ Treatment options for PNH are supportive care, allogeneic hematopoietic stem cell transplantation, and complement blockade by the anti-C5 monoclonal antibody (Soliris). Supportive care include use of oral iron to replace the large urinary losses; folate and vitamin B₁₂ supplementation; red blood cell transfusion when these measures do not maintain adequate hemoglobin levels; use of antibiotics to treat bacterial infections as soon as possible since infections can exacerbate hemolytic crises in patients with PNH; use of corticosteroids to reduce the

severity and duration of the hemolytic crises; use of Soliris as primary prophylaxis in patients with high PNH clone size (granulocyte close > 50%), high level of D dimer, pregnancy, perioperative condition, and other associated thrombophilia risk factors; and use of immunosuppressives in patients with PNH and aplastic anemia and bone marrow deficiency.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Ultomiris. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Ultomiris as well as the monitoring required for adverse events and long-term efficacy, approval requires Ultomiris to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Ultomiris is recommended in those who meet one of the following criteria:

FDA-Approved Indications

21. Atypical Hemolytic Uremic Syndrome. Approve for 1 year if the patient meets BOTH of the following (A and B):

7. Patient does not have Shiga toxin *Escherichia coli*-related hemolytic uremic syndrome; AND
8. The medication is prescribed by or in consultation with a nephrologist.

22. Generalized Myasthenia Gravis. Approve for the duration noted if the patient meets ONE of the following (A or B):

D) Initial therapy. Approve for 6 months if the patient meets ALL of the following (i, ii, iii, iv, v, vi, and vii):

viii. Patient is ≥ 18 years of age; AND

ix. Patient has confirmed anti-acetylcholine receptor antibody-positive generalized myasthenia gravis; AND

x. Patient meets BOTH of the following (a and b):

a) Myasthenia Gravis Foundation of America classification of II to IV; AND

b) Myasthenia Gravis Activities of Daily Living (MG-ADL) score of ≥ 6 ; AND

xi. Patient meets ONE of the following (a or b):

a) Patient previously received or is currently receiving pyridostigmine; OR

b) Patient has had inadequate efficacy, a contraindication, or significant intolerance to pyridostigmine; AND

xii. Patient meets ONE of the following (a or b):

a) Patient previously received or is currently receiving two different immunosuppressant therapies for ≥ 1 year; OR

b) Patient had inadequate efficacy, a contraindication, or significant intolerance to two different immunosuppressant therapies; AND

Note: Examples of immunosuppressant therapies include azathioprine, cyclosporine, mycophenolate mofetil, methotrexate, tacrolimus, and cyclophosphamide.

xiii. Patient has evidence of unresolved symptoms of generalized myasthenia gravis; AND

Note: Evidence of unresolved symptoms of generalized myasthenia gravis includes difficulty swallowing, difficulty breathing, or a functional disability resulting in the discontinuation of physical activity (e.g., double vision, talking, impairment of mobility).

xiv. The medication is prescribed by or in consultation with a neurologist.

E) Patient is Currently Receiving Ultomiris. Approve for 1 year if the patient meets ALL of the following (i, ii, and iii):

i. Patient is ≥ 18 years of age; AND

ii. According to the prescriber, patient is continuing to derive benefit from Ultomiris; AND

Note: Examples of benefit include reductions in exacerbations of myasthenia gravis; improvements in speech, swallowing, mobility, and respiratory function.

iii. The medication is prescribed by or in consultation with a neurologist.

23. Neuromyelitis Optica Spectrum Disorder. Approve for the duration noted if the patient meets ONE of the following (A or B):

C) Initial Therapy. Approve for 1 year if the patient meets ALL of the following (i, ii, and iii):

iv. Patient is ≥ 18 years of age; AND

v. Diagnosis was confirmed by a positive blood serum test for anti-aquaporin-4 antibody; AND

vi. The medication is prescribed by or in consultation with a neurologist.

D) Patient is Currently Receiving Ultomiris. Approve for 1 year if the patient meets ALL of the following criteria (i, ii, iii, and iv):

v. Patient is ≥ 18 years of age; AND

vi. Diagnosis was confirmed by a positive blood serum test for anti-aquaporin-4 antibody; AND

vii. According to the prescriber, patient has had clinical benefit from the use of Ultomiris ; AND

Note: Examples of clinical benefit include reduction in relapse rate, reduction in symptoms (e.g., pain, fatigue, motor function), and a slowing progression in symptoms.

viii. The medication is prescribed by or in consultation with a neurologist.

24. Paroxysmal Nocturnal Hemoglobinuria. Approve for the duration noted if the patient meets ONE of the following (A or B):

G) Initial therapy. Approve for 6 months if the patient meets BOTH of the following (i and ii):

iv. Diagnosis was confirmed by peripheral blood flow cytometry results showing the absence or deficiency of glycosylphosphatidylinositol (GPI)-anchored proteins on at least two cell lineages; AND

v. The medication is prescribed by or in consultation with a hematologist.

H) Patient is Currently Receiving Ultomiris. Approve for 1 year if the patient meets BOTH of the following (i and ii):

a. According to the prescriber, patient is continuing to derive benefit from Ultomiris; AND .

Note: Examples of benefit from Ultomiris include stabilization of hemoglobin levels, decreased transfusion requirements or transfusion independence, reductions in hemolysis, improvement in Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue score.

ii. The medication is prescribed by or in consultation with a hematologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Ultomiris is not recommended in the following situations:

- 3. Concomitant Use with Another Complement Inhibitor, Except Voydeya (danicopan tablets).** There is no evidence to support concomitant use of Ultomiris with another complement inhibitor, except Voydeya.

Note: Examples of complement inhibitors are Empaveli (pegcetacoplan subcutaneous injection), Fabhalta (iptacopan capsule), PiaSky (crovalimab-akkz intravenous infusion or subcutaneous injection), and Soliris (eculizumab intravenous infusion).

- 9. Concomitant Use with a Rituximab Product, a Neonatal Fc Receptor Blocker, or Zilbrysq (zilucoplan subcutaneous injection).** There is no evidence to support concomitant use of Ultomiris with a rituximab product, a neonatal Fc receptor blocker, or Zilbrysq.

Note: Examples of neonatal Fc receptor blockers are Rystiggo (rozanolixizumab-noli subcutaneous infusion), Vyvgart (efgartigimod alfa-fcab intravenous infusion), and Vyvgart Hytrulo (efgartigimod alfa and hyaluronidase-qvfc subcutaneous injection).

- 10. Concomitant Use with Enspryng (satralizumab-mwge subcutaneous injection) or Uplizna (inebilizumab-cdon intravenous infusion).** There is no evidence to support concomitant use of Ultomiris with Enspryng or Uplizna.

- 11.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Complement Inhibitors – Veopoz Prior Authorization Policy

- Veopoz™ (pozelimab-bbfg intravenous infusion and subcutaneous injection – Regeneron)

REVIEW DATE: 09/04/2024; selected revision 10/09/2024

OVERVIEW

Veopoz, a complement inhibitor, is indicated for the treatment of CD55-deficient protein-losing enteropathy, also known as CHAPLE disease, in adult and pediatric patients ≥ 1 year of age.¹

Disease Overview

CHAPLE (which stands for Complement Hyperactivation, Angiopathic thrombosis, and Protein-Losing Enteropathy) disease is an ultra-rare inherited immune disease that causes the complement system to become overactive.²⁻⁴ It is caused by biallelic loss-of-function mutations in the CD55 gene, which leads to loss of protein expression and can result in the complement system attacking the body's own cells. There are fewer than 100 patients diagnosed worldwide with CHAPLE disease; it is estimated to impact around 10 patients in the US. Symptoms can include abdominal pain, nausea, vomiting, diarrhea, loss of appetite, weight loss, impaired growth, and edema. Severe thrombotic vascular occlusions (blockage of blood vessels) can also occur among patients with CHAPLE disease, which can be life-threatening. The condition mainly impacts children, including infants, and is associated with morbidity and a higher risk of mortality.

Dosing Information

Veopoz is administered by a healthcare provider.¹ On Day 1, give a single 30 mg/kg loading dose by intravenous infusion. Day 8 and thereafter, the maintenance dose is 10 mg/kg as a subcutaneous injection once weekly. The maintenance dosage may be increased to 12 mg/kg once weekly if there is inadequate clinical response after at least three weekly doses (starting from Week 4). The maximum maintenance dosage is 800 mg once weekly. Doses exceeding 400 mg require two injections.

Safety

Veopoz has a Boxed Warning regarding serious meningococcal infections.¹ Life-threatening and fatal meningococcal infections have occurred in patients treated with complement inhibitors. Complete or update meningococcal vaccination at least 2 weeks before administering the first dose of Veopoz, unless the risks of delaying therapy outweigh the risks of developing meningococcal infection. Follow the most current Advisory Committee on Immunization Practices (ACIP) recommendations for meningococcal vaccination in patients receiving a complement inhibitor. Also, patients treated with Veopoz may be at increased risk for invasive disease caused by *Neisseria meningitidis*, even if they develop antibodies following vaccination. Patients treated with Veopoz may be at increased risk of developing serious infections due to *Streptococcus pneumoniae* and *Haemophilus influenzae* type b infections; administer related vaccinations according to ACIP guidelines.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Veopoz. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Veopoz as well as the monitoring required for adverse events and long-term efficacy, approval requires

09/04/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Veopoz to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Documentation: Documentation is required for use of Veopoz as noted in the criteria as **[documentation required]**. Documentation may include, but is not limited to, chart notes, laboratory data, genetic tests, and/or other information. Subsequent coverage reviews for a patient who has previously met the documentation requirement for the genetic test criterion in the *Complement Inhibitors – Veopoz Prior Authorization Policy* through the Coverage Review Department and who is requesting reauthorization, are NOT required to resubmit documentation for reauthorization regarding the genetic test criterion.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Veopoz is recommended in those who meet the following criteria:

FDA-Approved Indication

4. **CD55-Deficient Protein-Losing Enteropathy (CHAPLE Disease [Complement Hyperactivation, Angiopathic thrombosis, and Protein-Losing Enteropathy]).** Approve for the duration noted below if the patient meets ONE of the following (A or B):

- A) **Initial Therapy.** Approve for 3 months if the patient meets ALL of the following (i, ii, iii, iv, and v):

- i. Patient is ≥ 1 year of age; AND
- ii. Patient has had a genetic test confirming the diagnosis of CHAPLE disease with a biallelic CD55 loss-of-function mutation **[documentation required]**; AND
- iii. Patient meets BOTH of the following (a and b):
 - a) Patient has a serum albumin level ≤ 3.2 g/dL **[documentation required]**; AND
 - b) According to the prescribing physician, the patient has active disease and is experiencing one or more signs or symptoms within the last 6 months; AND
Note: Examples of signs and symptoms include abdominal pain, diarrhea, vomiting, peripheral edema, or facial edema.
- iv. Patient meets BOTH of the following (a and b):
 - a) Patient has received or is in compliance with updated meningococcal vaccinations according to the most current Advisory Committee on Immunization Practices recommendations; AND
 - b) Patient has received or is in compliance with updated vaccinations for the prevention of *Streptococcus pneumonia* and *Haemophilus influenza* type b infections according to the most current Advisory Committee on Immunization Practices guidelines; AND
- v. Medication is prescribed by a physician with expertise in managing CHAPLE disease; OR

- B) **Patient Currently Receiving Veopoz.** Approve for 1 year if the patient meets ALL of the following (i, ii, iii, and iv):

- i. Patient is ≥ 1 year of age; AND
- ii. Patient has had a genetic test confirming the diagnosis of CHAPLE disease with a biallelic CD55 loss-of-function mutation **[documentation required]**; AND
- iii. Medication is prescribed by a physician with expertise in managing CHAPLE disease; AND
- iv. Patient had experienced a response to therapy **[documentation required]**.
Note: Examples of a response to therapy include increased serum albumin levels, maintenance of serum albumin levels within a normal range, a reduction in albumin transfusions, increases in or maintenance of protein and/or immunoglobulin levels, improvement in clinical outcomes

after receipt of therapy (e.g., decreases in the frequency of problematic abdominal pain, bowel movement frequency, facial edema severity, and peripheral edema severity), reduced frequency in hospitalizations, increase in growth percentiles (e.g., body weight-for age and/or stature-for-age percentiles), and/or reduced use of corticosteroids.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Veopoz is not recommended in the following situations:

- 12. Concomitant Use with Other Complement Inhibitors.** In the pivotal study, use of other complement inhibitors was prohibited.
- 13.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Complement Inhibitors – Voydeya Prior Authorization Policy

- Voydeya™ (danicopan tablets – Alexion)

REVIEW DATE: 05/02/2024; selected revision 05/22/2024

OVERVIEW

Voydeya, a complement Factor D inhibitor, is indicated as add-on therapy to Soliris® (eculizumab intravenous infusion) or Ultomiris® (ravulizumab-cwvz intravenous infusion or subcutaneous injection) for the treatment of extravascular hemolysis in adults with paroxysmal nocturnal hemoglobinuria (PNH).

Voydeya has a Boxed Warning about serious infections caused by encapsulated bacteria.¹ Voydeya is only available through a restricted access program, Voydeya Risk Evaluation and Mitigation Strategy (REMS).

Disease Overview

Paroxysmal nocturnal hemoglobinuria (PNH) is a rare, genetic disorder of hematopoietic stem cells.^{2,3} The mutation in the X-linked gene phosphatidylinositol glycan class A (PIGA) results in a deficiency in the glycosylphosphatidylinositol (GPI) protein, which is responsible for anchoring other protein moieties to the surface of the erythrocytes. Loss of anchoring of these proteins causes cells to hemolyze and leads to complications such as hemolytic anemia, thrombosis, and peripheral blood cytopenias. PNH is a clinical diagnosis that should be confirmed with peripheral blood flow cytometry to detect the absence or severe deficiency of GPI-anchored proteins on at least two lineages.^{2,5} Prior to the availability of complement inhibitors, only supportive management, in terms of managing the cytopenias and controlling thrombotic risk were available. Supportive measures include platelet transfusion, immunosuppressive therapy for patients with bone marrow failure, use of erythropoietin for anemias, and aggressive anticoagulation.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Voydeya. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Voydeya as well as the monitoring required for adverse events and long-term efficacy, approval requires Voydeya to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Voydeya is recommended in those who meet the following criteria:

05/02/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

FDA-Approved Indication

- 25. Paroxysmal Nocturnal Hemoglobinuria.** Approve for the duration noted if the patient meets ONE of the following (A or B):
- I) Initial therapy.** Approve for 3 months if the patient meets ALL of the following (i, ii, iii, and iv):
- vi.** Patient is ≥ 18 years of age; AND
 - vii.** Paroxysmal nocturnal hemoglobinuria diagnosis was confirmed by peripheral blood flow cytometry results showing the absence or deficiency of glycosylphosphatidylinositol-anchored proteins on at least two cell lineages; AND
 - viii.** The medication is prescribed in combination with Soliris (eculizumab intravenous infusion) or Ultomiris (ravulizumab-cwvz intravenous infusion or subcutaneous injection); AND
 - ix.** According to the prescriber, patient has clinically significant extravascular hemolysis (while receiving Soliris or Ultomiris), as evidenced by objective laboratory findings.; AND
Note: Examples of objective laboratory findings include reduction in hemoglobin levels, elevated reticulocyte counts, increased transfusion requirements, transfusion-dependence.
 - x.** The medication is prescribed by or in consultation with a hematologist.
- J) Patient is Currently Receiving Voydeya.** Approve for 1 year if the patient meets ALL of the following (i, ii, iii, and iv):
- vii.** Patient is ≥ 18 years of age; AND
 - viii.** The medication is prescribed in combination with Soliris (eculizumab intravenous infusion) or Ultomiris (ravulizumab-cwvz intravenous infusion or subcutaneous injection); AND
 - ix.** According to the prescriber, patient is continuing to derive benefit from Voydeya; AND
Note: Examples of benefit include increase in or stabilization of hemoglobin levels, decreased transfusion requirements or transfusion independence, reductions in hemolysis, improvement in Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue score.
 - x.** The medication is prescribed by or in consultation with a hematologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Voydeya is not recommended in the following situations:

- 4. Concomitant Use with Empaveli (pegcetacoplan subcutaneous injection) or Fabhalta (iptacopan capsules).** There is no evidence to support concomitant use of Voydeya with Empaveli or Fabhalta.
- 14.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Complement Inhibitors – Zilbrysq Prior Authorization Policy

- Zilbrysq® (zilucoplan subcutaneous injection – UCB)

REVIEW DATE: 12/04/2024

OVERVIEW

Zilbrysq, a complement C5 inhibitor, is indicated for the treatment of **generalized myasthenia gravis** in adults who are anti-acetylcholine receptor antibody-positive.¹

Disease Overview

Myasthenia gravis is a chronic autoimmune neuromuscular disease that causes weakness in the skeletal muscles, which are responsible for breathing and moving parts of the body, including the arms and legs.² The hallmark of myasthenia gravis is muscle weakness that worsens after periods of activity and improves after periods of rest. Certain muscles such as those that control eye and eyelid movement, facial expression, chewing, talking, and swallowing are often involved in the disorder; however, the muscles that control breathing and neck and limb movements may also be affected. Acquired myasthenia gravis results from the binding of autoantibodies to components of the neuromuscular junction, most commonly the acetylcholine receptor.³

Clinical Efficacy

The efficacy of Zilbrysq was evaluated in 12-week, multicenter, randomized, double-blind placebo-controlled study (n = 174).^{1,4} All of the enrolled patients had anti-acetylcholine receptor antibody-positive generalized myasthenia gravis. In addition, patients had a Myasthenia Gravis Foundation of America (MGFA) clinical classification class II to IV and a Myasthenia Gravis-Activities of Daily Living (MG-ADL) total score of ≥ 6 . MG-ADL assesses the impact of generalized myasthenia gravis on daily functions of eight signs or symptoms that are typically impacted by this disease. Each sign or symptom is assessed on a 4-point scale; a higher score indicates greater impairment. At baseline, 85% of patients in each group received cholinesterase inhibitors, 63% received steroids, and 51% received non-steroidal immunosuppressive therapies, at stable doses. Patients were randomized to receive either Zilbrysq 0.3 mg/kg or placebo. The primary efficacy endpoint was a comparison of the change from baseline between treatment groups in the MG-ADL total score at Week 12. Statistically significantly greater improvement in the MG-ADL total score was observed in the Zilbrysq group compared with placebo: -4.39 points vs. -2.30 points, respectively ($P < 0.001$). Statistically significant improvement in the secondary efficacy endpoints were also observed in the Zilbrysq group vs. placebo.

Guidelines

An international consensus guidance for the management of myasthenia gravis was published in 2016.³ The guidelines recommend pyridostigmine for the initial treatment in most patients with myasthenia gravis. The ability to discontinue pyridostigmine can indicate that the patient has met treatment goals and may guide the tapering of other therapies. Corticosteroids or immunosuppressant therapy should be used in all patients with myasthenia gravis who have not met treatment goals after an adequate trial of pyridostigmine. Nonsteroidal immunosuppressant agents used in treatment of myasthenia gravis include azathioprine, cyclosporine, mycophenolate mofetil, methotrexate, and tacrolimus. It is usually necessary to maintain some immunosuppression for many years, sometimes for life. Plasma exchange and intravenous immunoglobulin can be used as short-term treatments in certain patients. A 2020 update to these guidelines provides new/additional recommendations for methotrexate, rituximab, and eculizumab intravenous

12/04/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

infusion (Soliris®, biosimilars).⁵ All recommendations should be considered extensions or additions to recommendations made in the initial international consensus guidance (2016). Oral methotrexate may be considered as a steroid-sparing agent in patients with generalized myasthenia gravis who have not tolerated or responded to steroid-sparing agents. Rituximab should be considered as an early therapeutic option in patients with anti-muscle-specific tyrosine kinase antibody-positive myasthenia gravis who have an unsatisfactory response to initial immunotherapy. Eculizumab should be considered in the treatment of severe, refractory, anti-acetylcholine receptor antibody-positive MG.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Zilbrysq. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Zilbrysq as well as the monitoring required for adverse events and long-term efficacy, approval requires Zilbrysq to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Zilbrysq is recommended in those who meet the following criteria:

FDA-Approved Indication

26. Generalized Myasthenia Gravis. Approve for the duration noted if the patient meets ONE of the following (A or B):

F) Initial therapy. Approve for 6 months if the patient meets ALL of the following (i, ii, iii, iv, v, vi, and vii):

xv. Patient is ≥ 18 years of age; AND

xvi. Patient has confirmed anti-acetylcholine receptor antibody-positive generalized myasthenia gravis; AND

xvii. Patient meets BOTH of the following (a and b):

a) Myasthenia Gravis Foundation of America classification of II to IV; AND

b) Myasthenia Gravis Activities of Daily Living (MG-ADL) score of ≥ 6 ; AND

xviii. Patient meets ONE of the following (a or b):

a) Patient received or is currently receiving pyridostigmine; OR

b) Patient has had inadequate efficacy, a contraindication, or significant intolerance to pyridostigmine; AND

xix. Patient meets ONE of the following (a or b):

a) Patient received or is currently receiving two different immunosuppressant therapies for ≥ 1 year; OR

b) Patient had inadequate efficacy, a contraindication, or significant intolerance to two different immunosuppressant therapies; AND

Note: Examples of immunosuppressant therapies tried include azathioprine, cyclosporine, mycophenolate mofetil, methotrexate, tacrolimus, and cyclophosphamide.

xx. Patient has evidence of unresolved symptoms of generalized myasthenia gravis; AND

Note: Evidence of unresolved symptoms of generalized myasthenia gravis includes difficulty swallowing, difficulty breathing, and a functional disability resulting in the discontinuation of physical activity (e.g., double vision, talking, impairment of mobility).

- xxi. The medication is being prescribed by or in consultation with a neurologist.
- G) Patient is Currently Receiving Zilbrysq. Approve for 1 year if the patient meets ALL of the following (i, ii, and iii):
- i. Patient is ≥ 18 years of age; AND
 - ii. According to the prescriber, patient is continuing to derive benefit from Zilbrysq; AND
Note: Examples of derived benefit include reductions in exacerbations of myasthenia gravis; improvements in speech, swallowing, mobility, and respiratory function.
 - iii. The medication is being prescribed by or in consultation with a neurologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Zilbrysq is not recommended in the following situations:

- 15. Concomitant Use with Another Complement Inhibitor, a Neonatal Fc Receptor Blocker, or a Rituximab Product.** There is no evidence to support concomitant use of Zilbrysq with another complement inhibitor, a neonatal Fc receptor blocker, or a rituximab product.
Note: Examples of complement inhibitors are eculizumab intravenous infusion (Soliris, biosimilars) and Ultomiris (ravulizumab-cwvz intravenous infusion or subcutaneous injection).
Note: Examples of Neonatal Fc receptor blockers are Rystiggo [rozanolixizumab-noli subcutaneous infusion) Vyvgart (efgartigimod alfa-fcab intravenous infusion), and Vyvgart Hytrulo (efgartigimod alfa and hyaluronidase-qvfc subcutaneous injection).
- 16.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Complement System Disorders – WHIM Syndrome – Xolremdi Prior Authorization Policy

- Xolremdi™ (mavoxiafor capsules – X4 Pharmaceuticals)

REVIEW DATE: 05/08/2024

OVERVIEW

Xolremdi, a CXC chemokine receptor 4 (CXCR4) antagonist, is indicated for the treatment of **WHIM syndrome** (warts, hypogammaglobulinemia, infections and myelokathexis) to increase the number of circulating mature neutrophils and lymphocytes in adults and children ≥ 12 years of age.¹

Disease Overview

WHIM syndrome is a rare autosomal primary immunodeficiency that causes hyperactivity with failure to down regulate the CXCR4 receptor.^{2,3} Most of the patients with WHIM syndrome are heterozygous carriers of mutations of CXCR4. Clinical presentation include recurrent bacterial infections and severe or chronic neutropenia that begins in infancy or early childhood. There is no cure for WHIM syndrome and prior to the approval of Xolremdi, treatment was based on patient's symptoms.²

Clinical Efficacy

The efficacy of Xolremdi for the treatment of WHIM syndrome has been evaluated in one pivotal study.^{1,4} The study included patients ≥ 12 years of age with genetically confirmed WHIM syndrome and confirmed absolute neutrophil count (ANC) ≤ 400 cells/ μ L or white blood cells (WBC) ≤ 400 cells/ μ L. The primary efficacy endpoint of the meantime above threshold ANC (TAT-ANC) at Week 52 assessment.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Xolremdi. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Xolremdi as well as the monitoring required for adverse events and long-term efficacy, initial approval requires Xolremdi to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

05/08/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Xolremdi is recommended in those who meet the following criteria:

FDA-Approved Indication

5. **WHIM syndrome.** Approve Xolremdi for the duration noted if the patient meets ONE of the following (A or B):

A) Initial Therapy. Approve for 1 year if the patient meets ALL of the following (i, ii, iii, and iv):

- i. Patient is ≥ 12 years of age; AND
- ii. Genetic testing confirms pathogenic and or likely pathogenic variants in the CXCR4 gene; AND
- iii. Patient meets ONE of the following (a or b):
 - a) At baseline, patient had an absolute neutrophil count ≤ 400 cells/ μ L; OR
 - b) At baseline, patient had a white blood cell count ≤ 400 cells/ μ L; AND
- iv. The medication is prescribed by or in consultation with an immunologist, hematologist or dermatologist.

B) Patient is Currently Receiving Xolremdi. Approve for 1 year if, according to the prescriber, the patient is continuing to derive benefit from Xolremdi as determined by the most recent objective measurement.

Note: Examples of objective measurements of a response to Xolremdi therapy are reduced frequency, duration, or severity of infections, less frequent treatment with antibiotics, fewer warts, or improved or stabilized clinical signs/symptoms of WHIM syndrome (e.g., absolute neutrophil count, white blood cell count, and absolute lymphocyte count).

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Xolremdi is not recommended in the following situations:

17. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

OVERVIEW

Compounded products are used for a **variety of indications from treating pain to hormone therapy**. The compounded formulations can contain just one active drug in a base vehicle or they may contain a combination of active drugs. Compounded medications are not FDA-approved, thus the FDA has limited regulatory authority over compounding pharmacies since they are licensed by their respective state board of pharmacy. Compounded medications also do not undergo the rigorous drug review process to demonstrate safe and effective use in patients that all commercially available prescription drugs must establish prior to widespread availability. Also, compounded medications generally do not have standardized dosages and duration for use; likewise, there are no standardized protocols to prepare each compound. For these reasons, compounded preparations are at a greater propensity to have batch-to-batch variability and the product sterility/purity cannot be guaranteed relative to the commercially available products.

Clinical Efficacy

There are very limited published controlled studies with established safety and efficacy data supporting use of compounded medications for any condition. The available efficacy data for the targeted topical compounds in this policy are described below.

Topical Ketamine

There are four randomized, placebo-controlled studies published assessing the use of compounded topical ketamine for neuropathic pain.¹⁻⁴ *Study 1* enrolled patients (n = 208) with chemotherapy-induced peripheral neuropathy and randomized them to either a placebo gel or a compounded mixture containing baclofen 10 mg, amitriptyline 40 mg, and ketamine 20 mg in a pluronic lecithin organogel vehicle base.¹ Patients applied the gel twice daily for 4 weeks. There was a trend towards improvement in the sensory neuropathy scale (primary endpoint) compared with placebo, though it was not statistically significant (P = 0.053). Statistically significant improvement was noted with the motor subscale (P = 0.021). *Study 2* enrolled patients (n = 92) with mixed neuropathic pain (i.e., diabetic neuropathy [n = 20/92], postherpetic neuralgia [n = 14/92], post-surgical/post-traumatic neuropathic pain [n = 58/92] with allodynia, hyperalgesia, or pinprick hyperesthesia) and evaluated the application of one of four topical creams: topical amitriptyline 2%, topical ketamine 1%, a combination of topical amitriptyline 2% and topical ketamine 1%, or placebo (vehicle base).² Patients applied 4 mL cream to the site of maximum pain three times daily (TID) for 3 weeks. Pain levels at the end of the study compared with baseline were not statistically significantly different between treatment groups. *Study 3* evaluated the efficacy of topical ketamine 5% cream applied TID for 4 weeks in patients (n = 17) with diabetic neuropathy.³ Seven different pain characteristics (i.e., intensity, sharpness, cold, hot, dull, sensitive, and itchy) were measured using a pain scale both before and after treatment. Diabetic pain measures were reduced in both treatment groups and the placebo effect was equally as strong as ketamine 5% cream. *Study 4* was a crossover trial that assessed the efficacy of (S)-ketamine 1% ointment or placebo applied four times daily for 15 days in patients (n = 12) with postherpetic neuralgia.⁴ There was a washout period of 7 days in-between crossover. A numerical verbal scale was used to assess pain scores and efficacy of therapy during three different clinic visits. There was no statistical significance in pain scores during treatments with (S)-ketamine 1% ointment or placebo.

One small randomized, double-blind, placebo-controlled study assessed the use of compounded topical ketamine in patients (n = 20) with complex regional pain syndrome (CRPS).⁵ CRPS has been described as a challenging pain syndrome usually starting after a trauma or surgery.⁶ CRPS can be classified into two types: patients with CRPS type 1 do not have demonstrable nerve lesions and type 2 is based on objective nerve damage, most commonly caused by severe trauma. CRPS type 1 has also been recognized as a

chronic neuropathic pain syndrome that typically develops in an extremity after tissue trauma. The above mentioned study⁵ concluded that topical ketamine did not lead to pain reduction in patients with CRPS, but it did reduce allodynia

Topical Gabapentin

There are no published data available with the use of compounded topical gabapentin for neuropathic pain.

The only published trial available is a retrospective study assessing the use of topical gabapentin 2% to 6% cream in women (n = 51) with vulvodynia (chronic, unexplained vulvar pain or discomfort, characterized by burning, stinging, irritation or rawness).⁷ After a minimum of 8 weeks of therapy with application of gabapentin cream TID, about 80% of the patients demonstrated at least a 50% improvement in their pain scores. The American College of Obstetricians and Gynecologist committee opinion (2016) [reaffirmed 2018] on persistent vulvar pain mention oral gabapentin as a therapy option, but do not mention compounded gabapentin.⁸

Topical Hyaluronic Acid Sodium Salt

Hyaluronic acid is a naturally occurring polysaccharide that is widely distributed in various body tissues.⁹ Sodium hyaluronate and other derivatives are used for a variety of conditions, such as osteoarthritis (OA) and as surgical aids in ophthalmic procedures. It is available commercially as FDA-approved products for intra-articular injections (e.g., Synvisc[®]) for the treatment of knee OA and for use as an ophthalmic surgical aid (e.g., Amvisc[™]). There are also multiple hyaluronic acid products available as intradermal injectable gel for use as wrinkle fillers in cosmetic procedures (e.g., Juvederm[®] XC). Over-the-counter (OTC) products can contain hyaluronic acid, including some artificial tear formulations and certain vaginal moisturizers.

Topical Corticosteroids – Fluticasone Propionate, Mometasone Furoate

Fluticasone propionate and mometasone furoate are corticosteroids which are used intranasally for the treatment of allergic and non-allergic rhinitis, by oral inhalation for the treatment of asthma and/or chronic obstructive pulmonary disease (COPD), and as topical preparations for the treatment of inflammatory and pruritic types of dermatoses and psoriasis.⁹ These two corticosteroids are available as FDA-approved, commercial products in the following strengths and dosage form: fluticasone propionate 0.05% cream and lotion, and 0.005% ointment; mometasone furoate 0.1% cream, lotion (topical solution), and ointment.

There are no published clinical trial data available for the use of compounded topical formulations of fluticasone propionate or mometasone furoate either alone or in combination with other products for the treatment of skin conditions. One small open-label study (n = 23) evaluated the use of intranasal irrigation of fluticasone propionate in patients with chronic rhinosinusitis following endoscopic sinus surgery.¹¹ The main intent of this study was to assess the effects of fluticasone on adrenal function (whether or not it was suppressed) and its effect on intraocular pressure (IOP). The irrigation solution was prepared by emptying a 3-mg capsule of fluticasone propionate (provided by a compounding pharmacy) into 240 mL isotonic saline solution (available OTC as Sinus Rinse[™] saline rinse kit) and used twice daily for 6 weeks. There were no significant changes with fluticasone irrigation use in measured salivary cortisol levels or IOP after 6 weeks. No other efficacy data are noted in this study.

Topical Nonsteroidal Anti-inflammatory Drugs (NSAIDs)

The other compounded topical drugs targeted in this policy – topical diclofenac, ketoprofen, flurbiprofen, meloxicam, and nabumetone – all belong to the NSAID drug class. These agents are generally used for the treatment of pain (e.g., OA, musculoskeletal pain). There are several topical NSAID formulations that are FDA-approved and commercially available. Topical diclofenac is commercially available as diclofenac sodium 3% gel, Voltaren[®] Arthritis 1% gel (OTC), diclofenac 1.5% and 2% topical solution, diclofenac

0.1% ophthalmic solution, diclofenac epolamine 1.3 % topical patch (Flector®), and Licart® topical patch.^{12-16,21} OTC Voltaren Arthritis gel is for the temporary relief of arthritis pain, and diclofenac topical solution is indicated for the treatment of OA of the knees.^{13,14} Topical flurbiprofen is commercially available as a 0.03% ophthalmic solution and it is indicated for the treatment of intraoperative miosis.¹⁷ The American College of Rheumatology (ACR) guidelines (2019) for hand, hip, and knee OA recommend topical NSAIDs for the treatment of hand and knee OA.¹⁸ As there are multiple FDA-approved topical NSAIDs, the guidelines do not address compounded products.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of the following compounded topical medications: ketamine, gabapentin, diclofenac, ketoprofen, flurbiprofen, meloxicam, nabumetone, hyaluronic acid derivatives, mometasone furoate, and fluticasone propionate. Due to the lack of robust clinical efficacy and safety data, in addition to the lack of standardized dosages and formulations, **approval is not recommended for any condition** for these non-FDA-approved topical compounded formulations of ketamine, gabapentin, diclofenac, ketoprofen, flurbiprofen, meloxicam, nabumetone, hyaluronic acid derivatives, mometasone furoate, and fluticasone propionate (either alone or in combination with other medications).

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

None.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of compounded topical formulations of ketamine, gabapentin, diclofenac, ketoprofen, flurbiprofen, meloxicam, nabumetone, hyaluronic acid derivatives, mometasone furoate, and fluticasone propionate (either alone or in combination with other medications) is not recommended in the following situations:

Topical Ketamine

73. Neuropathic Pain. There are published data available from four randomized, placebo-controlled studies assessing the efficacy of compounded topical ketamine, either alone or in combination with other agents (e.g., amitriptyline, baclofen) for the treatment of various types of neuropathic pain (e.g., peripheral neuropathy, diabetic neuropathy).¹⁻⁴ In summary, three of the four studies did not show any statistically significant efficacy differences compared with placebo. One study showed a trend towards improvement compared with placebo in patients with chemotherapy-induced peripheral neuropathy.¹ All of the other published data with topical ketamine use for neuropathic pain are based on case reports, open-label studies, or pilot studies.

74. Complex regional pain syndrome (CRPS). There are very limited published efficacy data available with topical ketamine for the treatment of CRPS. One small double-blind, placebo-controlled study assessed the efficacy of ketamine 10% cream in patients (n = 20) with CRPS type 1 (n = 18/20) and type 2 (n = 2/20) on two separate occasions.⁵ The primary aim was to determine whether topical ketamine inhibited sensory disturbances in the symptomatic limb of patients. Topical ketamine did not lead to pain reduction, but allodynia to brushing the skin was reduced. Most of the other published evidence for topical ketamine use for CRPS is based on case reports.

Topical Gabapentin

1. **Neuropathic Pain.** There are no published efficacy or safety data available with compounded topical formulations of gabapentin either alone or in combination with other drugs for use in neuropathic pain.
2. **Complex regional pain syndrome (CRPS).** There are no published efficacy or safety data available with topical gabapentin use for the treatment of CRPS.
3. **Vulvodynia.** There is one retrospective study that assessed the efficacy of topical gabapentin 2% to 6% in women (n = 51) with vulvodynia.⁷ Though topical gabapentin was effective in reducing pain in about 80% of women, these data are limited by small sample size and study design. Large randomized trials are needed to establish the efficacy of topical gabapentin for vulvodynia.

Topical NSAIDs (diclofenac, ketoprofen, flurbiprofen, nabumetone, and meloxicam)

1. **Arthritis (e.g., osteoarthritis [OA], rheumatoid arthritis [RA]).** There are no published data available with the use of compounded, non-FDA approved topical formulations of NSAIDs such as topical diclofenac, topical ketoprofen, topical meloxicam, topical nabumetone, and topical flurbiprofen, either alone or in combination with other agents for the treatment of arthritis, such as OA. FDA-approved, commercially available topical NSAIDs such as Voltaren 1% gel, and Pennsaid 1.5% topical solution are indicated for the treatment of OA and have substantial efficacy and safety data supporting their use.^{10,11} With the availability of effective and safe FDA-approved topical NSAIDs, the use of other compounded topical NSAIDs with no established efficacy and safety data is not recommended.

Topical Fluticasone Propionate and Topical Mometasone Furoate

1. **Use in various types of skin conditions (e.g., dermatitis, wound care).** There are very limited to no published efficacy or safety data available with non-FDA approved, compounded formulations of fluticasone and mometasone for the treatment of skin conditions.
2. **Cosmetic Use (e.g., scar therapy, for minimizing stretch marks).** Cosmetic use is excluded from coverage in a typical pharmacy benefit.
3. **Use as Intranasal Irrigation Solution for Chronic Rhinosinusitis.** Multiple small studies have assessed the use of fluticasone and mometasone nasal irrigations.^{11,19} Results are not definitive and larger studies are needed to analyze differences between nasal sprays vs. irrigation.¹⁹

Topical Hyaluronic Acid Derivatives

1. **Vaginal Atrophy.** Limited data are available with the use of compounded hyaluronic acid derivatives. According to the North American Menopause Society guidelines on genitourinary syndrome of menopause (2020), there is no evidence that products with hyaluronic acid have a greater benefit than nonhyaluronic acid lubricants or moisturizers.¹⁰ Additionally, vaginal products containing hyaluronic acid are available without a prescription.
2. **Osteoarthritis (OA).** There are no published efficacy data available to support the use of non-FDA - approved, compounded formulations of hyaluronic acid and its derivatives for use in any OA or other pain-related conditions. Hyaluronic acid intra-articular injections (e.g., Euflexxa) are available as FDA-approved products for the treatment of OA of the knee.⁹
3. **Use in Any Other Medical Condition, Including, But Not Limited to, Ophthalmic Procedures and Wound Care.** There are small studies showing some efficacy data surrounding the active hyaluronic acid ingredient²⁰, but there are no FDA-approved indications for topical hyaluronic use.

4. **Cosmetic Use (e.g., treatment of frown lines).** Cosmetic use is excluded from coverage in a typical pharmacy benefit.

PRIOR AUTHORIZATION POLICY

POLICY: Contraceptives – Phexxi Prior Authorization Policy

- Phexxi™ (lactic acid, citric acid, and potassium bitartrate vaginal gel – Evofem)

REVIEW DATE: 05/08/2024

OVERVIEW

Phexxi is indicated for the **prevention of pregnancy** in females of reproductive potential for use as an on-demand method of contraception.¹ Limitation of Use: Phexxi is not effective for the prevention of pregnancy when administered after intercourse.

Phexxi contains lactic acid, citric acid, and potassium bitartrate; *in vitro* studies show that a pH lowering effect and sperm motility reduction contribute to the activity of the product in the vagina.¹ Phexxi has been previously known under multiple names, such as Amphora, Acidform, and was historically available as an over-the-counter (OTC) personal lubricant.² The recommended dose of Phexxi is one pre-filled applicator (5 grams) vaginally administered immediately before or up to one hour before each act of vaginal intercourse.¹ If more than one act of vaginal intercourse occurs within one hour, an additional dose must be used.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Phexxi. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days.

Note: When compliance with the Affordable Care Act, HRSA Guidelines, and PHS Act section 2713 is required and the conditions for coverage listed under the Recommended Authorization Criteria are not met, approval is granted for the prevention of pregnancy if, according to the prescriber, other barrier methods of contraception would not be as medically appropriate for the patient as the requested drug.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Phexxi is recommended in those who meet the following criteria:

FDA-Approved Indication

- 6. Prevention of Pregnancy.** Approve for 6 months if the patient has tried THREE other barrier methods of contraception (i.e., diaphragms, condoms, spermicides, or sponges).

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Phexxi is not recommended in the following situations:

- 18. As a Personal Lubricant.** The ingredients in Phexxi were previously available and marketed as an OTC personal lubricant.² Phexxi is currently only indicated for prevention of pregnancy.¹

05/08/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- 19. Acute Episodes of Bacterial Vaginosis.** Low vaginal pH may provide a measure of protection against specific organisms.² In a pilot clinical study comparing Acidform gel with metronidazole gel for the treatment of symptomatic bacterial vaginosis, Acidform gel was significantly less effective.³
- 20. For Protection Against Human Immunodeficiency Virus (HIV) or any other Sexually Transmitted Infections.** Per Phexxi labeling, it does not protect against HIV infection or other sexually transmitted infections.¹
- 21.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Coronavirus Disease – Evusheld Prior Authorization Policy

- Evusheld™ (tixagevimab intramuscular injection and cilgavimab intramuscular injection – AstraZeneca)

REVIEW DATE: 02/07/2024

OVERVIEW

On December 8, 2021 the FDA issued an Emergency Use Authorization (EUA) for Evusheld for pre-exposure prophylaxis of coronavirus disease 2019 (COVID-19). Based on data showing that Evusheld is unlikely to be active against currently circulating variants of COVID-19, the FDA removed the EUA for Evusheld on January 26, 2023.⁴

Evusheld, a combination product containing two severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) spike protein-directed attachment inhibitors, received EUA for the **pre-exposure prophylaxis of COVID-19** in patients ≥ 12 years of age and weighing ≥ 40 kg:¹

- who are not currently infected with SARS-CoV-2 and who have not had a known recent exposure to an individual infected with SARS-CoV-2; AND
- who have moderate to severe immune compromise due to a medical condition or receipt of immunosuppressive medications or treatments and may not mount an adequate immune response to COVID-19 vaccination; OR
- for whom vaccination with any available COVID-19 vaccine, according to the approved or authorized schedule, is not recommended due to a of severe adverse reactions (e.g., severe allergic reaction) to a COVID-19 vaccine(s) and/or COVID-19 vaccine component(s).

Guidelines

The Infectious Disease Society of America (IDSA) and the National Institutes of Health (NIH) have developed treatment guidelines for the management of COVID-19 and each address the use of Evusheld.^{2,3} The NIH recommends against the use of Evusheld for the pre-exposure prophylaxis of COVID-19.² In addition, the IDSA states that the benefits of prophylaxis with Evusheld no longer outweigh the small but known risks associated with its use.³

POLICY STATEMENT

Due to the lack of clinical efficacy, **approval is not** recommended for Evusheld.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

None.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Evusheld is not recommended in the following situations:

- 22. Coronavirus Disease 2019 (COVID-19), Pre-Exposure Prophylaxis.** Approval is not recommended. The FDA has removed the EUA for Evusheld due to the high combined frequency of non-susceptible

02/07/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

SARS-CoV-2 variants to Evusheld nationally.⁴ According to the Centers for Disease Control and Prevention, the non-susceptible strains of SARS-CoV-2 are expected to account for > 90% of current infections. In addition, the NIH stated on January 30, 2023 that the prevalence of SARS-CoV-2 strains resistant to Evusheld is estimated to be > 97%.⁵ The NIH now recommends against the use of Evusheld for pre-exposure prophylaxis of COVID-19.

23. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Coronavirus Disease – Veklury Prior Authorization Policy

- Veklury® (remdesivir intravenous infusion – Gilead)

REVIEW DATE: 01/08/2025

OVERVIEW

Veklury, a severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) nucleotide analog RNA polymerase inhibitor, is indicated for the treatment of **coronavirus disease 2019 (COVID-19)** in patients from birth and weighing ≥ 1.5 kg, who are:

- Hospitalized, or
- Not hospitalized and have mild-to-moderate COVID-19, and are at high risk of progression to severe COVID-19, including hospitalization or death.¹

Guidelines

The Infectious Disease Society of America (IDSA) has developed treatment guidelines for the management of COVID-19 and each address the use of Veklury.² The IDSA guidelines recommend Veklury for hospitalized patients with COVID-19 who require supplemental oxygen. For patients receiving supplemental oxygen, Veklury is recommended for 5 days of treatment. The IDSA recommends against the initiation of Veklury in patients receiving invasive mechanical ventilation or extracorporeal membrane oxygenation (ECMO). In patients who require mechanical ventilation or ECMO after initiating Veklury, a full 10 day course of Veklury should be administered. The IDSA also recommends 3 days of Veklury for non-hospitalized patients with mild-to-moderate COVID-19 who are at high risk of progression.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Veklury. All approvals are provided for the duration noted below. All reviews will be forwarded to the Medical Director for evaluation.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Veklury is recommended in those who meet the following criteria:

FDA-Approved Indication

7. **Coronavirus Disease 2019 (COVID-19), Treatment.** Approve for the duration noted if the patient meets the following (A, B, and C):
- A) Patient weight is ≥ 1.5 kilograms; AND
 - B) Patient has tested positive for the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2); AND
 - C) Patient meets ONE of the following (i or ii):
 - i. Approve for 10 days if the patient is being treated in a hospital; OR
 - ii. Approve for 3 days if the patient meets BOTH of the following (a and b):
 - a) Patient is being treated in an outpatient setting; AND

01/08/2025

© 2025. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- b)** Patient is at high risk of progression to severe COVID-19, according to the prescriber.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Veklury is not recommended in the following situations:

- 24.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

REFERENCES

PRIOR AUTHORIZATION POLICY

POLICY: Corticosteroids (Intraarticular) – Zilretta Prior Authorization Policy

- Zilretta® (triamcinolone acetonide extended-release intraarticular injection – Pacira)

REVIEW DATE: 05/08/2024

OVERVIEW

Zilretta, an **extended-release** synthetic corticosteroid, is indicated as an intraarticular injection for the management of **osteoarthritis pain of the knee**.¹

Several other injectable corticosteroids (e.g., betamethasone sodium phosphate and betamethasone acetate, dexamethasone sodium phosphate, methylprednisolone acetate, and immediate-release triamcinolone acetonide) are indicated for intraarticular use for the management of osteoarthritic conditions.²⁻⁵

Dosing Information

Zilretta is administered as a single intraarticular injection that delivers 32 mg/5 mL.¹ Limitation of Use: The efficacy and safety of Zilretta for **repeat** administration have not been demonstrated.

Guidelines

Guidelines for the medical management of osteoarthritis of the hand, hip, and knee are available from the American College of Rheumatology (2019).⁶ Multiple non-pharmacological modalities are recommended for knee osteoarthritis, including exercise, self-management programs, weight loss, Tai Chi, and use of assistive devices (i.e., bracing or a cane). Pharmacologic therapy for knee osteoarthritis consists of acetaminophen, oral and topical non-steroidal anti-inflammatory drugs, tramadol, intraarticular corticosteroid injections, duloxetine, and topical capsaicin. In the guidelines, no distinction is made between the available intraarticular corticosteroid products or between short-acting and long-acting products.

The American Academy of Orthopaedic Surgeons practice guideline for the management of osteoarthritis of the knee (2021) states intraarticular corticosteroids could provide **short-term** relief for patients with symptomatic osteoarthritis of the knee.⁷ Additionally, extended-release intraarticular corticosteroids can be used over immediate-release to improve patient outcomes.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Zilretta. All approvals are provided for the duration noted below.

Documentation: Documentation is required for use of Zilretta as noted in the criteria as **[documentation required]**. Documentation may include, but is not limited to, chart notes, prescription claims records, prescription receipts, and/or other information.

Automation: None.

05/08/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Zilretta is recommended in those who meet the following criteria:

FDA-Approved Indication

- 8. Osteoarthritis Pain of the Knee.** Approve for one injection per treated knee if the patient meets ALL of the following (A, B, and C):
- A)** Diagnosis of the knee to be treated is confirmed by radiologic evidence of knee osteoarthritis; AND
Note: Examples of radiologic evidence include diagnosis based on x-ray, magnetic resonance imaging, computed tomography scan, and ultrasound.
 - B)** Patient has tried at least ONE intraarticular corticosteroid injection in the knee to be treated **[documentation required]**.
Note: Examples of intraarticular corticosteroid injections include immediate-release triamcinolone acetonide, betamethasone sodium phosphate/betamethasone acetate, dexamethasone sodium phosphate, and methylprednisolone acetate.
 - C)** Patient is not receiving re-treatment of knee(s) previously treated with Zilretta.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Zilretta is not recommended in the following situations:

- 25.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Crysvida Prior Authorization Policy

- Crysvida® (burosumab-twza subcutaneous injection – Ultragenyx/Kyowa)

REVIEW DATE: 08/07/2024

OVERVIEW

Crysvida, a fibroblast growth factor 23 (FGF23) blocking antibody, is indicated for:¹

- **Tumor-induced osteomalacia**, for treatment of FGF-related hypophosphatemia associated with phosphaturic mesenchymal tumors that cannot be curatively resected or localized in patients ≥ 2 years of age.
- **X-linked hypophosphatemia** in patients ≥ 6 months of age.

Disease Overview

Tumor-Induced Osteomalacia

Tumor-induced osteomalacia is an extremely rare condition caused by tumors that produce the phosphaturic hormone FGF23, which causes renal phosphate wasting, and ultimately leads to hypophosphatemia, rickets, and osteomalacia.² Tumor-induced osteomalacia is generally caused by small, slow-growing, benign phosphaturic mesenchymal tumors; complete resection of the tumor results in cure. However, in some cases, locating the tumor is not possible or the tumor may be inoperable. Patients usually present in adulthood with symptoms of fatigue, muscle weakness, and bone pain, which can lead to impaired mobility. They may also experience decreased bone mineral density and frequent fractures. Treatment of patients with inoperable or unidentifiable tumors has been phosphate supplementation and active vitamin D (e.g., calcitriol).

X-Linked Hypophosphatemia

X-linked hypophosphatemia is a condition that is believed to result from an inactivating genetic mutation in phosphate regulating endopeptidase on the X chromosome (PHEX).³⁻⁶ This mutation leads to increased levels of FGF23, which increases phosphate excretion and abnormal vitamin D metabolism, ultimately leading to hypophosphatemic rickets.^{3-5,7} Signs and symptoms of X-linked hypophosphatemia differ in pediatric patients who are still growing vs. adults whose epiphyseal plates have fused. In adults, symptoms include calcification of tendons, ligaments, and joint capsules; joint pain; impaired mobility; spontaneous dental abscesses; stress fractures; and sensorineural hearing loss. The X-linked hypophosphatemia diagnosis can be established in patients with a low serum phosphate concentration, a reduced tubular resorption of phosphate corrected for glomerular filtration rate (TmP/GFR), an inappropriate calcitriol level for the severity of hypophosphatemia, and/or by identification on molecular genetic testing of a hemizygous PHEX pathogenic variant in a male patient or a heterozygous PHEX pathogenic variant in a female patient. Genetic testing can provide a negative or positive confirmation in 70 to 90% of patients with suspected X-linked hypophosphatemia who lack a family.⁶ If a genetic test is unavailable, an elevated FGF23 level can also support the diagnosis. However, FGF23 levels may be influenced by other factors, particularly phosphate and vitamin D therapy. FGF23 levels may be elevated in several other forms of hypophosphatemic rickets as well. Finally, the normal range of FGF23 varies according to the assay used.

08/07/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Clinical Efficacy

Tumor-Induced Osteomalacia

Two studies evaluated the efficacy of Crysvida in patients with tumor-induced osteomalacia.^{1,8,9} Eligible patients were adults with a confirmed diagnosis of FGF23-related hypophosphatemia produced by an underlying tumor that was not amenable to surgical excision or could not be located. In addition to low baseline serum phosphorus, patients were also required to have a low TmP/GFR and a high FGF23 level. The vast majority of patients had previously received phosphate and active vitamin D therapy. Crysvida was found to increase the mean serum phosphorus level from baseline through Week 24 (Month 6) when levels stabilized.

X-Linked Hypophosphatemia

The efficacy of Crysvida for the treatment of X-linked hypophosphatemia was evaluated in several clinical trials in pediatric and adult patients with X-linked hypophosphatemia.¹ Eligible patients had baseline serum phosphorus levels less than the lower limit of normal for age.^{1,10-12} Across the studies, Crysvida was found to increase mean serum phosphorus levels significantly from baseline. Radiographic improvements and healing of fractures/pseudofractures were also observed. Sustained efficacy has been demonstrated out to Week 96.^{13,14} One additional study compared Crysvida with conventional therapy in patients 1 to 12 years of age with X-linked hypophosphatemia.¹⁵ Following 64 weeks of therapy, patients receiving Crysvida had demonstrated a significantly greater improvement in the Radiographic Global Impression of Change global score compared with the conventional therapy group. In patients 5 to 12 years of age, sustained efficacy has been observed for up to 160 weeks, while there are extension data up to 168 weeks in adults.¹⁶⁻¹⁹

GUIDELINES

Tumor-Induced Osteomalacia

An expert panel published global guidance for the recognition, diagnosis, and management of tumor-induced osteomalacia in 2023.²⁰ In patients who present with chronic muscle pain or weakness, fragility fractures, or bone pain, a serum phosphate measurement is recommended, along with a physical examination to establish features of myopathy and to identify masses that could potentially be causative tumors. Several other laboratory tests are recommended as well, including urine/serum phosphate, TmP/GFR, alkaline phosphatase, parathyroid hormone, 25-hydroxyvitamin D, 1,25(OH)₂D, and FGF23 (may be elevated or inappropriately normal). It is recommended that patients be referred to a specialist for diagnosis confirmation if tumor-induced osteomalacia is suspected. Tumor resection is recommended, but if the tumor is unresectable or unidentifiable, treatment with phosphate and active vitamin D or Crysvida is recommended.

X-Linked Hypophosphatemia

An expert panel has published Clinical Practice Recommendations for the Diagnosis and Management of X-linked hypophosphatemia (2019).⁶ It is recommended that a clinical diagnosis of X-linked hypophosphatemia be confirmed by genetic analysis of the PHEX gene if feasible. In regard to treatment, oral phosphate and active vitamin D (e.g., calcitriol) are recommended for symptomatic adults with X-linked hypophosphatemia. Crysvida therapy should be considered for the treatment of adults with X-linked hypophosphatemia with the following features: persistent bone/joint pain due to X-linked hypophosphatemia and/or osteomalacia that limits daily activities; pseudofractures or osteomalacia-related fractures; and insufficient response or refractory to oral phosphate and active vitamin D. If patients experience complications related to oral phosphate and active vitamin D, Crysvida is recommended as well.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Crysvita. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Crysvita as well as the monitoring required for adverse events and long-term efficacy, approval requires Crysvita to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Crysvita is recommended in those who meet one of the following criteria:

FDA-Approved Indications

1. Tumor-Induced Osteomalacia. Approve Crysvita for the duration noted if the patient meets ONE of the following (A or B):

A) Initial Therapy. Approve for 6 months if the patient meets ALL of the following (i, ii, iii, iv, v, vi, and vii):

- i.** Patient is ≥ 2 years of age; AND
- ii.** Patient has a mesenchymal tumor that cannot be curatively resected or identified/localized; AND
- iii.** Patient is currently exhibiting one or more signs or symptoms of tumor-induced osteomalacia, as determined by the prescriber; AND
Note: Examples of signs and symptoms of tumor-induced osteomalacia include bone pain, impaired mobility, muscle weakness, and fatigue.
- iv.** Patient has had a baseline serum phosphorus level that was below the normal range for age; AND
Note: “Baseline” is defined as prior to receiving any tumor-induced osteomalacia treatment, such as Crysvita, oral phosphate, or vitamin D therapy.
- v.** Patient has had a baseline tubular reabsorption of phosphate corrected for glomerular filtration rate (TmP/GFR) that was below the normal range for age and gender; AND
Note: “Baseline” is defined as prior to receiving any tumor-induced osteomalacia treatment, such as Crysvita, oral phosphate, or vitamin D therapy.
- vi.** Patient meets ONE of the following (a or b):
 - 1)** Patient has tried oral phosphate and calcitriol therapy; OR
 - 2)** Per the prescriber the patient has a contraindication to oral phosphate therapy, calcitriol therapy, or both; AND
- vii.** The medication is prescribed by or in consultation with an endocrinologist or nephrologist.

B) Patient is Currently Receiving Crysvita. Approve for 1 year if the patient is continuing to derive benefit from Crysvita as determined by the prescriber.

Note: Examples of a response to Crysvita therapy are increased phosphorus levels, decreased symptoms of bone pain and/or muscle weakness, and increased mobility.

- 2. X-Linked Hypophosphatemia.** Approve Crysvisa for the duration noted if the patient meets ONE of the following (A or B):
- A) Initial Therapy.** Approve for 1 year if the patient meets ALL of the following (i, ii, iii, and iv):
- i.** Patient has had a baseline serum phosphorus level that was below the normal range for age; AND
Note: “Baseline” is defined as prior to receiving any X-linked hypophosphatemia treatment, such as Crysvisa, oral phosphate, or vitamin D therapy.
 - ii.** Patient meets ONE of the following (a or b):
 - a)** Patient has had a baseline tubular reabsorption of phosphate corrected for glomerular filtration rate (TmP/GFR) that was below the normal range for age and gender; OR
Note: “Baseline” is defined as prior to receiving any X-linked hypophosphatemia treatment, such as Crysvisa, oral phosphate, or vitamin D therapy.
 - b)** Patient has had a genetic test confirming the diagnosis of X-linked hypophosphatemia via identification of a PHEX pathogenic variant; AND
 - iii.** If the patient is ≥ 18 years of age, the patient meets BOTH of the following (a and b):
 - a)** Patient is currently exhibiting one or more signs or symptoms of X-linked hypophosphatemia, as determined by the prescriber; AND
Note: Examples of signs and symptoms of X-linked hypophosphatemia in patients ≥ 18 years of age include fractures/pseudofractures, bone and joint pain, muscle weakness, and impaired mobility.
 - b)** Patient meets ONE of the following (1 or 2):
 - 1)** Patient has tried oral phosphate and calcitriol therapy; OR
 - 2)** Per the prescriber the patient has a contraindication to oral phosphate therapy, calcitriol therapy, or both; AND
 - iv.** The medication is prescribed by or in consultation with an endocrinologist or nephrologist.
- B) Patient is Currently Receiving Crysvisa.** Approve for 1 year if the patient is continuing to derive benefit from Crysvisa as determined by the prescriber.
Note: Examples of a response to Crysvisa therapy are increased phosphorus levels, radiographic improvement in deformities, healing of fractures/pseudofractures, reduction in the incidence of new fractures/pseudofractures.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Crysvisa is not recommended in the following situations:

- 1. Chronic Kidney Disease, Severe Renal Impairment or End Stage Renal Disease.** Crysvisa is contraindicated in patients with severe renal impairment or end stage renal disease.¹ These patients often have abnormal mineral metabolism which may be associated with FGF23. However, Crysvisa has not been formally studied for the treatment of patients with chronic kidney disease who have elevations of FGF23 impacting phosphate regulation.^{1,9}
- 2. Epidermal Nevus Syndrome (including Cutaneous Skeletal Hypophosphatemia Syndrome).** More data are necessary to establish the efficacy and safety of Crysvisa in patients with epidermal nevus syndrome. Patients with epidermal nevus syndrome were eligible to enroll in one of the Phase II tumor-induced osteomalacia studies of Crysvisa.⁹ However, no patients with epidermal nevus syndrome enrolled. There are a few case reports of Crysvisa in patients with cutaneous skeletal hypophosphatemia syndrome (a variant of epidermal nevus syndrome).^{21,22} However, more data are needed to support the use of Crysvisa for this indication.

3. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Cushing's – Isturisa Prior Authorization Policy

- Isturisa® (osilodrostat tablets – Recordati Rare Diseases)

REVIEW DATE: 04/19/2024

OVERVIEW

Isturisa, a cortisol synthesis inhibitor, is indicated for the treatment of **Cushing's disease** in adults for whom pituitary surgery is not an option or has not been curative.¹

Disease Overview

Cushing's syndrome refers to the general state of excessive levels of cortisol (hypercortisolism) in the blood.^{2,3} Hypercortisolism can occur for reasons that are either endogenous or exogenous in nature (e.g., Cushing's disease, cortisol-containing medications, adrenal gland tumor, certain cancers). Cushing's disease (hypercortisolism caused by pituitary adenomas) is the most common type of adrenocorticotrophic hormone (ACTH)-dependent Cushing's syndrome. Treatment for Cushing's syndrome requires a multi-modal approach. The goals of treatment are normalization of cortisol excess, long-term disease control, avoidance of recurrence, and reversal of clinical features.⁴

Guidelines

The Endocrine Society published clinical practice guidelines (2015) for the treatment of Cushing's syndrome.⁵ Isturisa is not addressed in the guidelines. First-line treatment involves resection of the tumor, unless surgery is not possible or is unlikely to meaningfully reduce excess glucocorticoid levels. In patients with ACTH-dependent Cushing's syndrome who underwent non-curative surgery or for whom surgery was not possible, the guidelines advocate several second-line therapies (e.g., repeat transsphenoidal surgery, radiotherapy, medical therapy, and bilateral adrenalectomy). For Cushing's disease, the guidelines recommend all medical therapies as second-line options after transsphenoidal surgery: steroidogenesis inhibitors (ketoconazole tablets, Metopirone® [metyrapone capsules], Lysodren® [mitotane tablets], etomidate injection) in patients either with or without radiotherapy/radiosurgery; pituitary-directed medical treatments (cabergoline tablets, Signifor® [pasireotide subcutaneous injection]) in patients who are not surgical candidates or who have persistent disease; and mifepristone tablets (Korlym®, generic) in patients with diabetes or glucose intolerance who are not surgical candidates or who have persistent disease after transsphenoidal surgery.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Isturisa. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Isturisa as well as the monitoring required for adverse events and long-term efficacy, approval requires Isturisa to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Isturisa is recommended in those who meet one of the following criteria:

FDA-Approved Indication

- 27. Cushing's Disease.** Approve for 1 year if the patient meets ALL of the following (A, B, and C):
- A) Patient is ≥ 18 years of age; AND
 - B) According to the prescriber, the patient is not a candidate for surgery or surgery has not been curative; AND
- Note: For a patient with endogenous Cushing's syndrome awaiting surgery or therapeutic response after radiotherapy, see *Other Uses with Supportive Evidence*.
- C) The medication is prescribed by or in consultation with an endocrinologist or a physician who specializes in the treatment of Cushing's disease.

Other Uses with Supportive Evidence

- 28. Endogenous Cushing's Syndrome.** Approve for 1 year if the patient meets ALL of the following (A, B, C, and D):
- A) Patient is ≥ 18 years of age; AND
 - B) Patient meets ONE of the following (i, ii, or iii)
 - i. According to the prescriber, the patient is not a candidate for surgery or surgery has not been curative; OR
 - ii. Patient is awaiting surgery for **endogenous Cushing's Syndrome**; OR
 - iii. Patient is awaiting therapeutic response after radiotherapy for **endogenous Cushing's Syndrome**; AND
 - C) Patient meets ONE of the following (i or ii):
 - i. Patient has tried one of ketoconazole tablets, mifepristone tablets (Korlym, generic), Metopirone (metyrapone capsules), Lysodren (mitotane tablets), Signifor (pasireotide subcutaneous injection), or Signifor LAR (pasireotide intramuscular injection) for the treatment of endogenous Cushing's syndrome; OR
 - ii. Patient is currently receiving Isturisa; AND
 - D) The medication is prescribed by or in consultation with an endocrinologist or a physician who specializes in the treatment of endogenous Cushing's syndrome.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Isturisa is not recommended in the following situations:

- 26.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Cushing's – Mifepristone Prior Authorization Policy

- Korlym® (mifepristone 300 mg tablets – Corcept, generic)

REVIEW DATE: 04/19/2024

OVERVIEW

Mifepristone, a cortisol receptor blocker, is indicated to control hyperglycemia secondary to hypercortisolism in adults with **endogenous Cushing's syndrome** who have type 2 diabetes mellitus or glucose intolerance and have failed surgery or are not candidates for surgery.¹

Mifepristone should not be used for the treatment of type 2 diabetes mellitus unrelated to endogenous Cushing's syndrome.¹

Disease Overview

Cushing's syndrome refers to the general state of excessive levels of cortisol (hypercortisolism) in the blood.^{2,3} Hypercortisolism can occur for reasons that are either endogenous or exogenous in nature (e.g., Cushing's disease, cortisol-containing medications, adrenal gland tumor, certain cancers). Cushing's disease (hypercortisolism caused by pituitary adenomas) is the most common type of adrenocorticotropic hormone (ACTH)-dependent Cushing's syndrome. Treatment for Cushing's syndrome requires a multi-modal approach. The goals of treatment are normalization of cortisol excess, long-term disease control, avoidance of recurrence, and reversal of clinical features.⁴

Guidelines

The Endocrine Society published clinical practice guidelines (2015) for the treatment of Cushing's syndrome.⁵ First-line treatment involves resection of the tumor, unless surgery is not possible or is unlikely to meaningfully reduce excess glucocorticoid levels. In patients with ACTH-dependent Cushing's syndrome who underwent non-curative surgery or for whom surgery was not possible, the guidelines advocate several second-line therapies (e.g., repeat transsphenoidal surgery, radiotherapy, medical therapy, and bilateral adrenalectomy). For Cushing's disease, the guidelines recommend all medical therapies as second-line options after transsphenoidal surgery: steroidogenesis inhibitors (ketoconazole tablets, Metopirone® [metyrapone capsules], Lysodren® [mitotane tablets], etomidate injection) in patients either with or without radiotherapy/radiosurgery; pituitary-directed medical treatments (cabergoline tablets, Signifor® [pasireotide subcutaneous injection]) in patients who are not surgical candidates or who have persistent disease; and mifepristone tablets (Korlym®, generic) in patients with diabetes or glucose intolerance who are not surgical candidates or who have persistent disease after transsphenoidal surgery.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of mifepristone. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with mifepristone as well as the monitoring required for adverse events and long-term efficacy, approval requires mifepristone to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of mifepristone is recommended in those who meet the following criteria:

FDA-Approved Indication

1. **Endogenous Cushing's Syndrome.** Approve for 1 year if the patient meets ALL of the following (A, B, C, D, and E):
 - A) Patient is ≥ 18 years of age; AND
 - B) Mifepristone is being used to control hyperglycemia secondary to hypercortisolism in patients who have type 2 diabetes mellitus or glucose intolerance; AND
 - C) Patient meets ONE of the following (i, ii, or iii):
 - iv. According to the prescriber, the patient is not a candidate for surgery or surgery has not been curative; OR
 - v. Patient is awaiting surgery for **endogenous Cushing's Syndrome**; OR
 - vi. Patient is awaiting therapeutic response after radiotherapy for **endogenous Cushing's Syndrome**; AND
 - D) Patient meets ONE of the following (i or ii):
 - i. Patient has tried one of ketoconazole tablets, Metopirone (metyrapone capsules), Lysodren (mitotane tablets), Signifor (pasireotide subcutaneous injection), or Signifor LAR (pasireotide intramuscular injection) for the treatment of endogenous Cushing's syndrome; OR
 - ii. Patient is currently receiving mifepristone; AND
 - E) The medication is prescribed by or in consultation with an endocrinologist or a physician who specializes in the treatment of Cushing's syndrome.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of mifepristone is not recommended in the following situations:

27. **Type 2 Diabetes Not Associated with Endogenous Cushing's Syndrome.** Mifepristone should not be used for the treatment of type 2 diabetes unrelated to endogenous Cushing's syndrome.¹
28. **Psychotic Features of Psychotic Depression.** Mifepristone has been used to treat the psychotic features of psychotic depression. Individual trials have demonstrated variable efficacy results.^{6,7} In some of the studies comparing mifepristone with placebo, various statistically significant improvements in psychiatric symptoms have been noted with mifepristone relative to placebo; however, the methodology and statistical analyses of some studies have been questioned. Data are inconclusive.
29. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Cushing's – Recorlev Prior Authorization Policy

- Recorlev® (levoketoconazole tablets – Xeris)

REVIEW DATE: 04/19/2024

OVERVIEW

Recorlev, a cortisol synthesis inhibitor, is indicated for the treatment of endogenous hypercortisolemia in adults with **Cushing's syndrome** for whom surgery is not an option or has not been curative. Recorlev was approved through the 505(b)(2) pathway and as such relied upon existing safety and efficacy information for ketoconazole tablets to support approval. Recorlev contains levoketoconazole as the active ingredient. Levoketoconazole is the 2S, 4R-enantiomer derived from racemic ketoconazole.

Cushing's syndrome refers to the general state of excessive levels of cortisol (hypercortisolism) in the blood.^{2,3} Hypercortisolism can occur for reasons that are either endogenous or exogenous in nature (e.g., Cushing's disease, cortisol-containing medications, adrenal gland tumor, certain cancers). Cushing's disease (hypercortisolism caused by pituitary adenomas) is the most common type of adrenocorticotrophic hormone (ACTH)-dependent Cushing's syndrome. Treatment for Cushing's syndrome requires a multi-modal approach. The goals of treatment are normalization of cortisol excess, long-term disease control, avoidance of recurrence, and reversal of clinical features.⁴

Guidelines

The Endocrine Society published clinical practice guidelines (2015) for the treatment of Cushing's syndrome.⁵ Recorlev is not addressed in the guidelines. First-line treatment involves resection of the tumor unless surgery is not possible or is unlikely to meaningfully reduce excess glucocorticoid levels. In patients with ACTH-dependent Cushing's syndrome who underwent non-curative surgery or for whom surgery was not possible, the guidelines advocate several second-line therapies (e.g., repeat transsphenoidal surgery, radiotherapy, medical therapy, and bilateral adrenalectomy). For Cushing's disease, the guidelines recommend all medical therapies as second-line options after transsphenoidal surgery: steroidogenesis inhibitors (ketoconazole, Metopirone® [metyrapone capsules], Lysodren® [mitotane tablets], etomidate) in patients either with or without radiotherapy/radiosurgery; pituitary-directed medical treatments (cabergoline, Signifor® [pasireotide subcutaneous injection]) in patients who are not surgical candidates or who have persistent disease; and mifepristone tablets (Korlym®, generic) in patients with diabetes or glucose intolerance who are not surgical candidates or who have persistent disease after transsphenoidal surgery.

A 2021 guideline update does recognize Recorlev as an investigational drug for the treatment of Cushing's syndrome, but did not give recommendations for therapy placement within existing medications.⁶

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Recorlev. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Recorlev as well as the monitoring required for adverse events and long-term efficacy, approval requires Recorlev to be prescribed by or in consultation with a physician who specializes in the condition being treated.

04/19/2024

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Recorlev is recommended in those who meet the following criteria:

FDA-Approved Indication

- 29. Endogenous Cushing's Syndrome.** Approve for 1 year if the patient meets ALL of the following (A, B, C, D, and E):
- E)** Patient is ≥ 18 years of age; AND
 - F)** Patient has hypercortisolemia; AND
 - G)** Patient meets ONE of the following (i, ii, OR iii)
 - a. According to the prescriber, the patient is not a candidate for surgery or surgery has not been curative; OR
 - b. Patient is awaiting surgery for **endogenous Cushing's Syndrome**; OR
 - c. Patient is awaiting therapeutic response after radiotherapy for **endogenous Cushing's Syndrome**; AND
 - H)** Patient has tried ketoconazole tablets; AND
 - I)** The medication is prescribed by or in consultation with an endocrinologist or a physician who specializes in the treatment of endogenous Cushing's syndrome.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Recorlev is not recommended in the following situations:

- 30. Fungal Infections.** Recorlev is not approved for the treatment of fungal infections.¹
- 31.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Cushing's – Signifor Prior Authorization Policy

- Signifor™ (pasireotide subcutaneous injection – Novartis)

REVIEW DATE: 04/19/2024

OVERVIEW

Signifor, a somatostatin analog, is indicated for the treatment of **Cushing's disease** in adults for whom pituitary surgery is not an option or has not been curative.¹

Disease Overview

Cushing's syndrome refers to the general state of excessive levels of cortisol (hypercortisolism) in the blood.^{2,3} Hypercortisolism can occur for reasons that are either endogenous or exogenous in nature (e.g., Cushing's disease, cortisol-containing medications, adrenal gland tumor, certain cancers). Cushing's disease (hypercortisolism caused by pituitary adenomas) is the most common type of adrenocorticotrophic hormone (ACTH)-dependent Cushing's syndrome. Treatment for Cushing's syndrome requires a multi-modal approach. The goals of treatment are normalization of cortisol excess, long-term disease control, avoidance of recurrence, and reversal of clinical features.⁴

Guidelines

The Endocrine Society published clinical practice guidelines (2015) for the treatment of Cushing's syndrome.⁵ First-line treatment involves resection of the tumor, unless surgery is not possible or is unlikely to meaningfully reduce excess glucocorticoid levels. In patients with ACTH-dependent Cushing's syndrome who underwent non-curative surgery or for whom surgery was not possible, the guidelines advocate several second-line therapies (e.g., repeat transsphenoidal surgery, radiotherapy, medical therapy, and bilateral adrenalectomy). For Cushing's disease, the guidelines recommend medical therapies as second-line options after transsphenoidal surgery: steroidogenesis inhibitors (ketoconazole tablets, Metopirone® [metyrapone capsules], Lysodren® [mitotane tablets], etomidate injection) in patients either with or without radiotherapy/radiosurgery; pituitary-directed medical treatments (cabergoline tablets, Signifor) in patients who are not surgical candidates or who have persistent disease; and mifepristone tablets (Korlym®, generic) in patients with diabetes or glucose intolerance who are not surgical candidates or who have persistent disease after transsphenoidal surgery.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Signifor. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Signifor as well as the monitoring required for adverse events and long-term efficacy, approval requires Signifor to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Signifor is recommended in those who meet one of the following criteria:

FDA-Approved Indication

- 30. Cushing's Disease.** Approve for the duration noted below if the patient meets ONE of the following criteria (A or B):
- A) Initial Therapy. Approve for 4 months if the patient meets ALL of the following (i, ii, and iii):
- i. Patient is ≥ 18 years of age; AND
 - ii. According to the prescriber, the patient is not a candidate for surgery or surgery has not been curative; AND
Note: For patients with endogenous Cushing's syndrome awaiting surgery or therapeutic response after radiotherapy, see *Other Uses with Supportive Evidence*.
 - iii. The medication is prescribed by or in consultation with an endocrinologist or a physician who specializes in the treatment of Cushing's syndrome.
- B) Patient is Currently Receiving Signifor/Signifor LAR. Approve for 1 year if the patient has had a response, as determined by the prescriber; and patient is continuing therapy to maintain response.

Other Uses with Supportive Evidence

- 2. Endogenous Cushing's Syndrome.** Approve for 1 year if the patient meets ALL of the following (A, B, and C):
- A) Patient is ≥ 18 years of age; AND
- B) Patient meets ONE of the following (i, ii, or iii):
- i. According to the prescriber, the patient is not a candidate for surgery or surgery has not been curative; OR
 - ii. Patient is awaiting surgery for **endogenous Cushing's Syndrome**; OR
 - iii. Patient is awaiting therapeutic response after radiotherapy for **endogenous Cushing's Syndrome**; AND
- C) The medication is prescribed by or in consultation with an endocrinologist or a physician who specializes in the treatment of Cushing's syndrome.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Signifor is not recommended in the following situations:

- 32.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Cystic Fibrosis – Bronchitol Prior Authorization Policy

- Bronchitol® (mannitol oral inhalation powder – Pharmaxis/Chiesi)

REVIEW DATE: 02/07/2024

OVERVIEW

Bronchitol, a sugar alcohol, is indicated as add-on maintenance therapy to improve pulmonary function in patients ≥ 18 years of age with **cystic fibrosis** (CF).¹

Safety

Bronchitol can cause bronchospasm, which can be severe in susceptible patients.¹ Therefore, Bronchitol is contraindicated in individuals who fail to pass the Bronchitol Tolerance Test. Prior to prescribing Bronchitol, the Bronchitol Tolerance Test must be administered and performed under the supervision of a healthcare practitioner who is able to manage acute bronchospasm, to identify patients who are suitable candidates for Bronchitol maintenance therapy. For patients who have passed the Bronchitol Tolerance Test, the recommended dosage of Bronchitol is 400 mg twice a day by oral inhalation (the contents of 10 capsules administered individually) via the inhaler. A short-acting bronchodilator should be administered by oral inhalation, 5 to 15 minutes before every dose of Bronchitol. Bronchitol should be taken once in the morning and once in the evening, with the later dose taken at least 2 to 3 hours before bedtime.

Guidelines

Bronchitol is not addressed in US guidelines for CF. Guidelines from the CF Foundation (2013) in the US strongly recommend chronic use of Pulmozyme® (dornase alfa inhalation solution) in patients ≥ 6 years of age with moderate to severe disease to improve lung function and quality of life, and reduce exacerbations. Pulmozyme is also recommended for chronic use in patients ≥ 6 years of age with asymptomatic or mild disease to improve lung function and reduce exacerbations. Chronic use of hypertonic saline is also recommended in individuals with CF who are ≥ 6 years of age to improve lung function and quality of life and reduce exacerbations.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Bronchitol. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Bronchitol as well as the monitoring required for adverse events and long-term efficacy, approval requires Bronchitol to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Bronchitol is recommended in those who meet the following criteria:

FDA-Approved Indication

9. **Cystic Fibrosis.** Approve for 1 year if the patient meets the following (A, B, C, D, and E):
- A) Patient is ≥ 18 years of age; AND
 - B) Patient has tried hypertonic saline; AND
 - C) Patient has passed the Bronchitol Tolerance Test; AND
 - D) Patient will pre-medicate with a short-acting bronchodilator; AND
 - E) The medication is prescribed by or in consultation with a pulmonologist or a physician who specializes in the treatment of cystic fibrosis.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Bronchitol is not recommended in the following situations:

33. **Concomitant Use with Hypertonic Saline.** Bronchitol has not been studied in combination with hypertonic saline.³⁻⁵
34. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Cystic Fibrosis – Pulmozyme Prior Authorization Policy

- Pulmozyme® (dornase alfa inhalation solution – Genentech/Roche)

REVIEW DATE: 05/15/2024

OVERVIEW

Pulmozyme, a recombinant human deoxyribonuclease I, is indicated in conjunction with standard therapies for the management of patients with **cystic fibrosis** to improve pulmonary function.¹

Guidelines

According to Patient Registry data compiled by the Cystic Fibrosis Foundation (2022), Pulmozyme is used by the vast majority of patients with cystic fibrosis.² Guidelines from the Cystic Fibrosis Foundation (2007, updated in 2013) address the chronic use of medications for management of lung health in cystic fibrosis patients ≥ 6 years of age.^{3,4} These guidelines recommend Pulmozyme use for patients with cystic fibrosis regardless of disease severity to improve lung function and reduce exacerbations. Separate guidelines have addressed Pulmozyme use in younger patients.^{5,6} Although efficacy data are lacking in patients < 5 years of age, safety and tolerability have been established in patients as young as 3 months.^{1,6} Cystic Fibrosis Foundation guidelines for infants < 2 years of age (2009) and children between 2 and 5 years of age (2016) support Pulmozyme use in these populations based on individual circumstances.^{5,6}

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Pulmozyme. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Pulmozyme as well as the monitoring required for adverse events and long-term efficacy, approval requires Pulmozyme to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Pulmozyme is recommended in those who meet the following criteria:

FDA-Approved Indication

1. **Cystic Fibrosis.** Approve for 1 year if the medication is prescribed by or in consultation with a pulmonologist or a physician who specializes in the treatment of cystic fibrosis.

05/15/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Pulmozyme is not recommended in the following situations:

1. **Asthma.** Mucus hypersecretion may be mediated by a variety of causes, including inflammation, irritation, stimulation, or mucus-producing tumors.⁷ However, efficacy of Pulmozyme is not established for conditions other than cystic fibrosis.¹⁰ In a pilot study of patients with severe acute asthma (n = 50), there was no significant difference in forced expiratory volume in 1 second (FEV₁) with Pulmozyme use vs. placebo.^{8,10}
3. **Bronchiectasis, Idiopathic.** A multicenter, double-blind, randomized, placebo-controlled 24-week trial (n = 349) examined the effect of Pulmozyme vs. placebo in patients with idiopathic bronchiectasis (i.e., bronchiectasis not related to cystic fibrosis).⁹ Patients in the Pulmozyme arm experienced worsened lung function and more frequent pulmonary exacerbations vs. placebo. The authors concluded that Pulmozyme should not be used in this population. Another small double-blind, placebo-controlled, Phase II trial (n = 14) examined Pulmozyme in adults with non-cystic fibrosis bronchiectasis. Pulmozyme failed to show any significant change in any of the outcome variables or in sputum transportability.^{10,11}
4. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Cystic Fibrosis Transmembrane Conductance Regulator – Alyftrek Prior Authorization Policy

- Alyftrek™ (vanzacaftor/tezacaftor/deutivacaftor tablets – Vertex)

REVIEW DATE: 01/02/2025

OVERVIEW

Alyftrek is a combination of deutivacaftor, a cystic fibrosis transmembrane regulator (CFTR) potentiator, tezacaftor, and vanzacaftor. It is indicated for the **treatment of cystic fibrosis (CF)** in patients ≥ 6 years of age who have at least one F508del mutation or another responsive mutation in the CFTR gene.¹

If the patient's genotype is unknown, an FDA-cleared CF mutation test should be used to confirm the presence of at least one indicated mutation.¹

Table 1 lists responsive CFTR mutations based on clinical response, and/or *in vitro* data in Fischer Rat Thyroid cells or human bronchial endothelial cells, or based on extrapolation of efficacy.

Table 1. List of CFTR Gene Mutations that are Responsive to Alyftrek.¹

Table 1 (continued). List of CFTR Gene Mutations that are Responsive to Alyftrek.¹

CFTR – Cystic Fibrosis Transmembrane Conductance Regulator.

Guidelines

Alyftrek is not addressed in available guidelines. The most current treatment recommendations are the Standards of Care for CFTR variant-specific therapy for people with CF, from the European Cystic Fibrosis Society (2023).² However, the Standards do not reflect the currently approved age indications for Kalydeco® (ivacaftor tablets and oral granules) [≥ 1 months of age], Orkambi® [lumacaftor/ivacaftor tablets and oral granules] (≥ 1 year of age), or Trikafta® [elixacaftor/tezacaftor/ivacaftor; ivacaftor tablets and oral granules] [≥ 2 years of age]. In general, Trikafta is recommended over other agents where indications overlap. The Standards recommend Trikafta in patients ≥ 6 years of age with CF who are homozygous or heterozygous for F508del. In patients with one or more responsive non-F508del variant, Kalydeco, Symdeko® (tezacaftor/ivacaftor and ivacaftor tablets), or Trikafta are recommended. Kalydeco is recommended in patients ≥ 4 months of age with eligible CFTR gene variants. Orkambi is recommended for patients 2 to 5 years of age who are homozygous for F508del. Of note, the Standards state that after diagnosis, repeat sweat testing provides evidence of treatment effect on CFTR activity, but does not predict clinical response. The European Cystic Fibrosis Society Standards for establishing and maintaining health (2024) note that people with CF with eligible CFTR gene variants should be offered CFTR modulator therapy.⁵

According to the CF Foundation (2017), CF is diagnosed when an individual has both a clinical presentation of CF and evidence of CFTR dysfunction.^{3,4} Clinical presentation of CF includes a positive newborn screening, signs and/or symptoms of CF, and/or family history of CF. To establish a diagnosis of CF, sweat chloride tests should be considered first, then CFTR genetic analysis (CFTR genotype), and then CFTR physiologic tests (nasal potential difference [NPD] or intestinal current measurement [ICM]). However, tests of CFTR function are not always done in this order. All individuals diagnosed with CF should have a sweat chloride test and CFTR genetic analysis performed.

In a patient with a sweat chloride test ≥ 60 mmol/L, CF diagnosis is established and in patients with a sweat chloride test < 30 mmol/L, a diagnosis of CF is unlikely.^{3,4} Rarely, patients with a sweat chloride < 30 mmol/L may be considered to have CF if alternatives are excluded and other confirmatory tests (genetic and physiologic testing) support CF. In patients with a sweat chloride test of ≥ 30 to < 60 mmol/L, CFTR genetic analysis is undertaken. If the genetic analysis identifies two CF-causing CFTR mutations, CF is diagnosed, if no CFTR mutations are identified, a diagnosis of CF is unlikely. In patients with a CFTR genotype that is undefined or of varying clinical consequence, full gene CFTR sequencing (if not already performed) or CFTR physiologic testing is performed (NPD or ICM). If only one CFTR variant is identified on limited analysis, full gene CFTR sequencing should be performed. CF is possible if both alleles possess CF-causing, undefined, or mutation of varying clinical consequence mutations; CF is unlikely if only no CF-causing mutations are found. If results of the NPD or ICM show CFTR dysfunction, CF is diagnosed; when testing is unavailable or equivocal, the diagnosis of CF is not resolved, and when results of the physiologic testing show CFTR function is preserved, a diagnosis of CF is considered unlikely. It is recommended that patients with challenging diagnoses be evaluated at an accredited CF Foundation Care Center.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Alyftrek. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Alyftrek as well as the monitoring required for adverse events and long-term efficacy, approval requires Alyftrek to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Alyftrek is recommended in those who meet the following criteria:

FDA-Approved Indication

10. Cystic Fibrosis. Approve for 1 year if the patient meets ALL of the following (A, B, C, D, and E):

A) Patient is ≥ 6 years of age; AND

B) Patient has at least ONE of the following variants in the cystic fibrosis conductance regulator gene that is considered to be a pathogenic or likely pathogenic variant: F508del, A455E, G551D, L1077P, R352Q, S549N, V754M, D1152H, G85E, L206W, R75Q, S549R, W1098C, H1054D, M1101K, S1159F, S945L, W1282R, G1244E, I336K, R1066H, S1251N, V562I, Y563N, 1507_1515del9, E116Q, G424S, I556V, P140S, R334L, T1053I, 2183A→G, E193K, G463V, I601F, P205S, R334Q, T1086I, 3141del9, E292K, G480C, I618T, P499A, R347H, T1246I, 3195del6, E403D, G480S, I807M, P5L, R347L, T1299I, 3199del6, E474K, G551A, I980K, P574H, R347P, T338I, 546insCTA, E56K, G551S, K1060T, P67L, R352W, T351I, A1006E, E588V, G576A, K162E, P750L, R516G, T604I, A1067P, E60K, G576A;R668C, K464E, P99L, R516S, V1153E, A1067T, E822K, G622D, L1011S, Q1100P, R553Q, V1240G, A107G, E92K, G628R, L102R, Q1291R, R555G, V1293G, A120T, F1016S, G91R, L1065P, Q1313K, R560S, V201M, A234D, F1052V, G970D, L1324P, Q237E, R560T, V232D, A309D, F1074L, G970S, L1335P, Q237H, R668C, V392G, A349V, F1099L, H1085P, L137P, Q359R, R709Q, V456A, A46D, F1107L, H1085R, L1480P, Q372H, R74Q, V456F, A554E, F191V, H1375P, L15P, Q452P, R74W, V520F, A559T, F200I, H139R, L165S, Q493R, R74W;D1270N, V603F, A559V, F311del, H199R, L320V, Q552P, R74W;V201M, W361R, A561E, F311L, H199Y, L333F, Q98R,

C) Patient meets at least ONE of the following (i, ii, or iii):

- i.** Positive cystic fibrosis newborn screening test; OR
- ii.** Family of cystic fibrosis; OR
- iii.** Clinical presentation consistent with signs and symptoms of cystic fibrosis; AND

Note: Examples of clinical presentation of cystic fibrosis include but are not limited to meconium ileus, sino-pulmonary symptoms (e.g., persistent cough, wheezing, pulmonary function tests consistent with obstructive airway disease, excess sputum production), bronchiectasis, sinusitis, failure to thrive, pancreatic insufficiency.

D) Patient has evidence of abnormal cystic fibrosis transmembrane conductance regulator function as demonstrated by at least ONE of the following (i, ii, or iii):

- i.** Elevated sweat chloride test; OR
- ii.** Two cystic fibrosis-causing cystic fibrosis transmembrane conductance regulator mutations; OR
- iii.** Abnormal nasal potential difference; AND

E) The medication is prescribed by or in consultation with a pulmonologist or a physician who specializes in the treatment of cystic fibrosis.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Alyftrek is not recommended in the following situations:

35. Cystic Fibrosis, Patient with Unknown Cystic Fibrosis Transmembrane Conductance Regulator Gene Mutation. An FDA-cleared cystic fibrosis mutation test should be used to detect the presence of at least one indicated mutation prior to use of Alyftrek.¹

36. Combination Therapy with other Cystic Fibrosis Transmembrane Conductance Regulator Modulator(s). Alyftrek contains tezacaftor, which is a component of Symdeko[®] (tezacaftor/ivacaftor tablets; ivacaftor tablets) and Trikafta[®] (elexacaftor/tezacaftor/ivacaftor; ivacaftor tablets and granules). Note: Examples of other cystic fibrosis transmembrane conductance regulator modulators are: Kalydeco[®] (ivacaftor tablets and oral granules), Orkambi[®] (lumacaftor/ivacaftor tablets and oral granules), Symdeko[®] (tezacaftor/ivacaftor; ivacaftor tablets), Trikafta[®] (elexacaftor/tezacaftor/ivacaftor; ivacaftor tablets and oral granules).

- 37. Infertility.** Alyftrek is indicated for the treatment of cystic fibrosis in patients ≥ 6 years of age who have at least one F508del mutation or another responsive mutation in the cystic fibrosis transmembrane conductance regulator gene.

Note: A patient with a diagnosis of cystic fibrosis should be reviewed using criteria for the FDA-approved indication, above.

- 38.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Cystic Fibrosis Transmembrane Conductance Regulator – Kalydeco Prior Authorization Policy

- Kalydeco® (ivacaftor tablets and oral granules – Vertex)

REVIEW DATE: 02/07/2024; selected revision 04/10/2024 and 01/02/2025

OVERVIEW

Kalydeco, a cystic fibrosis transmembrane conductance regulator (CFTR) potentiator, is indicated for the treatment of **cystic fibrosis (CF)** in patients ≥ 1 month of age who have one mutation in the CFTR gene that is responsive to Kalydeco based on clinical and/or *in vitro* assay data.¹

In patients with unknown genotype, an FDA-cleared CF mutation test should be used to detect the presence of the CFTR mutation followed by verification with bidirectional sequencing when recommended by the mutation test instructions for use.¹ Kalydeco is not effective in patients with CF who are homozygous for the F508del mutation in the CFTR gene. A patient must have at least one CFTR mutation responsive to Kalydeco to be indicated. Table 1 lists mutations that are responsive to Kalydeco based on 1) a positive clinical response and/or 2) *in vitro* data in Fischer rat thyroid cells indicating that Kalydeco increases chloride transport to $\geq 10\%$ over baseline (% of normal).

Table 1. List of CFTR Gene Mutations that Produce CFTR Protein and are Responsive to Kalydeco.¹

CFTR – Cystic fibrosis transmembrane conductance regulator.

Guidelines

The most current treatment recommendations are the Standards of Care for CFTR variant-specific therapy for people with CF, from the European Cystic Fibrosis Society (2023).² However, the Standards do not reflect the currently approved age indications for Kalydeco (≥ 1 months of age), Orkambi® (lumacaftor/ivacaftor tablets and oral granules) [≥ 1 year of age], or Trikafta® (elexacaftor/tezacaftor/ivacaftor; ivacaftor tablets and oral granules) [≥ 2 years of age]. In general, Trikafta is recommended over other agents where indications overlap. The Standards recommend Trikafta in patients ≥ 6 years of age with CF who are homozygous or heterozygous for F508del. In patients with one or more responsive non-F508del variant, Kalydeco, Symdeko® (tezacaftor/ivacaftor; ivacaftor tablets), or Trikafta are recommended. Kalydeco is recommended in patients ≥ 4 months of age with eligible CFTR gene variants. Orkambi is recommended for patients 2 to 5 years of age who are homozygous for F508del. Of note, the Standards state that after diagnosis, repeat sweat testing provides evidence of treatment effect on CFTR activity, but does not predict clinical response. The European Cystic Fibrosis Society Standards for establishing and maintaining health (2024) note that people with CF with eligible CFTR gene variants should be offered CFTR modulator therapy.⁶

According to the CF Foundation (2017), CF is diagnosed when an individual has both a clinical presentation of CF and evidence of CFTR dysfunction.^{4,5} Clinical presentation of CF includes a positive newborn screening, signs and/or symptoms of CF, and/or family history of CF. To establish a diagnosis of CF, sweat chloride tests should be considered first, then CFTR genetic analysis (CFTR genotype), and then CFTR physiologic tests (nasal potential difference [NPD] or intestinal current measurement [ICM]). However, tests of CFTR function are not always done in this order. All individuals diagnosed with CF should have a sweat chloride test and CFTR genetic analysis performed.

In a patient with a sweat chloride test ≥ 60 mmol/L, CF diagnosis is established and in patients with a sweat chloride test < 30 mmol/L, a diagnosis of CF is unlikely.^{4,5} Rarely, patients with a sweat chloride < 30 mmol/L may be considered to have CF if alternatives are excluded and other confirmatory tests (genetic and physiologic testing) support CF. In patients with a sweat chloride test of ≥ 30 to < 60 mmol/L, CFTR genetic analysis is undertaken. If the genetic analysis identifies two CF-causing CFTR mutations, CF is diagnosed, if no CFTR mutations are identified, a diagnosis of CF is unlikely. In patients with a CFTR genotype that is undefined or of varying clinical consequence, full gene CFTR sequencing (if not already performed) or CFTR physiologic testing is performed (NPD or ICM). If only one CFTR variant is identified on limited analysis, full gene CFTR sequencing should be performed. CF is possible if both alleles possess CF-causing, undefined, or mutation of varying clinical consequence mutations; CF is unlikely if only no CF-causing mutations are found. If results of the NPD or ICM show CFTR dysfunction, CF is diagnosed; when testing is unavailable or equivocal, the diagnosis of CF is not resolved, and when results of the physiologic testing show CFTR function is preserved, a diagnosis of CF is considered unlikely. It is recommended that patients with challenging diagnoses be evaluated at an accredited CF Foundation Care Center.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Kalydeco. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Kalydeco as well as the monitoring required for adverse events and efficacy, approval requires Kalydeco to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Kalydeco is recommended in those who meet the following criteria:

FDA-Approved Indication

11. Cystic Fibrosis. Approve for 1 year if the patient meets ALL of the following (A, B, C, D and E):

- A) Patient is ≥ 1 month of age; AND
- B) Patient has at least ONE of the following mutations in the cystic fibrosis transmembrane conductance regulator gene that is considered to be a pathogenic or likely pathogenic variant: E56K, P67L, R74W, D110E, D110H, R117C, E193K, L206W, R347H, R352Q, A455E, D579G, S945L, S977F, F1052V, K1060T, A1067T, G1069R, R1070Q, R1070W, F1074L, D1152H, D1270N, G551D, G178R, S549N, S549R, G551S, G1244E, S1251N, S1255P, G1349D, 2789+5G $\rightarrow$ A, 3272-26A $\rightarrow$ G, 3849+10kbC $\rightarrow$ T, 711+3A $\rightarrow$ G, E831X, R117H, A120T, A234D, A349V, D192G, D924N, E882K, F311L, F311del, F508C, F508C;S1251N, G178E, G194R, G314E, G576A, G970D, G1249R, H939R, H1375P, I148T, I175V, I807M, I1027T, I1139V, L320V, L967S, L997F, L1480P, M152V, M952I, M952T, Q237E, Q237H, Q359R, Q1291R, R75Q, R117G, R117L, R117P, R170H, R347L, R553Q, R668C, R792G, R933G, R1162L, R1283M, S589N, S737F, S1159F, S1159P, T338I, T1053I, V232D, V562I, V754M, V1293G, W1282R, Y1014C, or Y1032C; AND
- C) Patient meets at least ONE of the following (i, ii, or iii):
 - i. Positive cystic fibrosis newborn screening test; OR
 - ii. Family of cystic fibrosis; OR
 - iii. Clinical presentation consistent with signs and symptoms of cystic fibrosis; AND
Note: Examples of clinical presentation of cystic fibrosis include but are not limited to meconium ileus, sino-pulmonary symptoms (e.g., persistent cough, wheezing, pulmonary function tests consistent with obstructive airway disease, excess sputum production), bronchiectasis, sinusitis, failure to thrive, pancreatic insufficiency.
- D) Patient has evidence of abnormal cystic fibrosis transmembrane conductance regulator function as demonstrated by at least ONE of the following (i, ii, or iii):
 - i. Elevated sweat chloride test; OR
 - ii. Two cystic fibrosis-causing cystic fibrosis transmembrane conductance regulator mutations; OR
 - iii. Abnormal nasal potential difference; AND
- E) The medication is prescribed by or in consultation with a pulmonologist or a physician who specializes in the treatment of cystic fibrosis.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Kalydeco is not recommended in the following situations:

1. **Cystic Fibrosis, Patient Homozygous for the F508del Mutation in the Cystic Fibrosis Transmembrane Conductance Regulator Gene.** Efficacy results from a double-blind, placebo controlled trial in patients with cystic fibrosis who were homozygous for the F508del mutation in the cystic fibrosis transmembrane regulator gene showed no statistically significant difference in forced expiratory volume in 1 second (FEV₁) over 16 weeks of Kalydeco treatment compared with placebo.¹ In a Phase II trial in patients homozygous for the F508del mutation (n = 112), Kalydeco did not result in an improvement in FEV₁ relative to placebo.³

- 75. Cystic Fibrosis, Patient with Unknown Cystic Fibrosis Transmembrane Conductance Regulator Gene Mutation.** An FDA-cleared cystic fibrosis mutation test should be used to detect the presence of the cystic fibrosis transmembrane conductance regulator mutation prior to use of Kalydeco.¹
- 76. Combination Therapy with Other Cystic Fibrosis Transmembrane Conductance Regulator Modulator(s).** Orkambi® (lumacaftor/ivacaftor tablets and oral granules), Symdeko® (tezacaftor/ivacaftor; ivacaftor tablets), and Trikafta® (elexacaftor/tezacaftor/ivacaftor; ivacaftor tablets and oral granules).contain ivacaftor, the active agent in Kalydeco and therefore are not indicated in combination with Kalydeco.
Note: Examples of other cystic fibrosis transmembrane conductance regulator modulators are: Alyftrek™ (vanzacaftor/tezacaftor/deutivacaftor tablets), Orkambi® (lumacaftor/ivacaftor tablets and oral granules), Symdeko® (tezacaftor/ivacaftor; ivacaftor tablets), Trikafta® (elexacaftor/tezacaftor/ivacaftor; ivacaftor tablets and oral granules).
- 77. Infertility.** Kalydeco is indicated for the treatment of cystic fibrosis in a patient $\geq$ 1 month of age who has one mutation in the cystic fibrosis transmembrane conductance regulator gene that is responsive to Kalydeco based on clinical and/or *in vitro* assay data.¹
Note: A patient with a diagnosis of cystic fibrosis should be reviewed using criteria for the FDA-approved indication, above.
- 78.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Cystic Fibrosis Transmembrane Conductance Regulator – Orkambi Prior Authorization Policy

- Orkambi® (lumacaftor/ivacaftor tablets and oral granules – Vertex)

REVIEW DATE: 07/10/2024; selected revision 01/02/2025

OVERVIEW

Orkambi, a combination of lumacaftor and ivacaftor, is indicated for the treatment of **cystic fibrosis (CF)** in patients ≥ 1 year of age who are homozygous for the F508del mutation in the cystic fibrosis transmembrane conductance regulator (CFTR) gene.¹

If the patient's genotype is unknown, an FDA-cleared cystic fibrosis mutation test should be used to detect the presence of the F508del mutation on both alleles of the CFTR gene. The efficacy and safety of Orkambi have not been established in patients with cystic fibrosis other than those homozygous for the F508del mutation. Orkambi contains a unique chemical entity, lumacaftor, which is a CFTR corrector that increases trafficking of F508del CFTR to the cell surface, and ivacaftor (the same active ingredient contained in Kalydeco® [ivacaftor tablets and oral granules]), a CFTR potentiator that enhances chloride transport of CFTR on the cell surface. The F508del mutation in CFTR causes cystic fibrosis by limiting the amount of CFTR protein that reaches the epithelial cell surface.

Guidelines

The most current treatment recommendations are the Standards of Care for CFTR variant-specific therapy for people with CF, from the European Cystic Fibrosis Society (2023).⁴ However, the Standards do not reflect the currently approved age indications for Kalydeco® (ivacaftor tablets and oral granules) [≥ 1 months of age], Orkambi (≥ 1 year of age), or Trikafta® (elexacaftor/tezacaftor/ivacaftor; ivacaftor co-packaged tablets and granules) [≥ 2 years of age]. In general, Trikafta is recommended over other agents where indications overlap. The Standards recommend Trikafta in patients ≥ 6 years of age with CF who are homozygous or heterozygous for F508del. In patients with one or more responsive non-F508del variant, Kalydeco, Symdeko® (tezacaftor/ivacaftor tablets; ivacaftor tablets), or Trikafta are recommended. Kalydeco is recommended in patients ≥ 4 months of age with eligible CFTR gene variants. Orkambi is recommended for patients 2 to 5 years of age who are homozygous for F508del. Of note, the Standards state that after diagnosis, repeat sweat testing provides evidence of treatment effect on CFTR activity, but does not predict clinical response. The European Cystic Fibrosis Society Standards for establishing and maintaining health (2024) note that people with CF with eligible CFTR gene variants should be offered CFTR modulator therapy.⁵

According to the CF Foundation (2017), CF is diagnosed when an individual has both a clinical presentation of CF and evidence of CFTR dysfunction.^{2,3} Clinical presentation of CF includes a positive newborn screening, signs and/or symptoms of CF, and/or family history of CF. To establish a diagnosis of CF, sweat chloride tests should be considered first, then CFTR genetic analysis (CFTR genotype), and then CFTR physiologic tests (nasal potential difference [NPD] or intestinal current measurement [ICM]). However, tests of CFTR function are not always done in this order. All individuals diagnosed with CF should have a sweat chloride test and CFTR genetic analysis performed.

In a patient with a sweat chloride test ≥ 60 mmol/L, CF diagnosis is established and in patients with a sweat chloride test < 30 mmol/L, a diagnosis of CF is unlikely.^{2,3} Rarely, patients with a sweat chloride < 30

07/10/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

mmol/L may be considered to have CF if alternatives are excluded and other confirmatory tests (genetic and physiologic testing) support CF. In patients with a sweat chloride test of ≥ 30 to < 60 mmol/L, CFTR genetic analysis is undertaken. If the genetic analysis identifies two CF-causing CFTR mutations, CF is diagnosed, if no CFTR mutations are identified, a diagnosis of CF is unlikely. In patients with a CFTR genotype that is undefined or of varying clinical consequence, full gene CFTR sequencing (if not already performed) or CFTR physiologic testing is performed (NPD or ICM). If only one CFTR variant is identified on limited analysis, full gene CFTR sequencing should be performed. CF is possible if both alleles possess CF-causing, undefined, or mutation of varying clinical consequence mutations; CF is unlikely if only no CF-causing mutations are found. If results of the NPD or ICM show CFTR dysfunction, CF is diagnosed; when testing is unavailable or equivocal, the diagnosis of CF is not resolved, and when results of the physiologic testing show CFTR function is preserved, a diagnosis of CF is considered unlikely. It is recommended that patients with challenging diagnoses be evaluated at an accredited CF Foundation Care Center.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Orkambi. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Orkambi as well as the monitoring required for adverse events and long-term efficacy, approval requires Orkambi to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Orkambi is recommended in those who meet the following criteria:

FDA-Approved Indication

12. Cystic Fibrosis, Homozygous for the F508del Mutation in the Cystic Fibrosis Transmembrane Conductance Regulator Gene. Approve for 1 year if the patient meets ALL of the following (A, B, C, D, and E):

- A) Patient is ≥ 1 year of age; AND
- B) Patient has TWO copies of the F508del mutation in the cystic fibrosis transmembrane conductance regulator gene; AND
- C) Patient meets at least ONE of the following (i, ii, or iii):
 - i. Positive cystic fibrosis newborn screening test; OR
 - ii. Family of cystic fibrosis; OR
 - iii. Clinical presentation consistent with signs and symptoms of cystic fibrosis; AND
Note: Examples of clinical presentation of cystic fibrosis include but are not limited to meconium ileus, sino-pulmonary symptoms (e.g., persistent cough, wheezing, pulmonary function tests consistent with obstructive airway disease, excess sputum production), bronchiectasis, sinusitis, failure to thrive, pancreatic insufficiency.
- D) Patient has evidence of abnormal cystic fibrosis transmembrane conductance regulator function as demonstrated by at least ONE of the following (i, ii, or iii):
 - i. Elevated sweat chloride test; OR
 - ii. Two cystic fibrosis-causing cystic fibrosis transmembrane conductance regulator mutations; OR
 - iii. Abnormal nasal potential difference; AND

07/10/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- E) The medication is prescribed by or in consultation with a pulmonologist or a physician who specializes in the treatment of cystic fibrosis.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Orkambi is not recommended in the following situations:

- 39. Cystic Fibrosis, Heterozygous for the F508del Mutation in the Cystic Fibrosis Transmembrane Conductance Regulator Gene.** Orkambi is not indicated for a patient with only one copy of the F508del mutation in the cystic fibrosis transmembrane conductance regulator gene.¹
- 79. Combination Therapy with Other Cystic Fibrosis Transmembrane Conductance Regulator Modulator(s).** Orkambi contains ivacaftor, the active agent in Kalydeco[®] (tablets and oral granules) and therefore is not indicated in combination with Kalydeco. Symdeko[®] (tezacaftor/ivacaftor tablets; ivacaftor tablets) and Trikafta[®] (elexacaftor/tezacaftor/ivacaftor; ivacaftor co-packaged tablets and granules) contain ivacaftor and are therefore not indicated in combination with Orkambi.
Note: Examples of other cystic fibrosis transmembrane conductance regulator modulators are: Alyftrek[™] (vanzacaftor/tezacaftor/deutivacaftor tablets), Kalydeco (ivacaftor tablets and oral granules), Symdeko (tezacaftor/ivacaftor; ivacaftor tablets), Trikafta (elexacaftor/tezacaftor/ivacaftor; ivacaftor co-packaged tablets and granules).
- 3. Infertility.** Orkambi is indicated for the treatment of cystic fibrosis in a patient ≥ 1 year of age who is homozygous for the F508del mutation in the cystic fibrosis transmembrane regulator gene.¹
Note: A patient with a diagnosis of cystic fibrosis should be reviewed using criteria for the FDA-approved indication, above.
- 4.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Cystic Fibrosis Transmembrane Conductance Regulator – Symdeko Prior Authorization Policy

- Symdeko® (tezacaftor/ivacaftor and ivacaftor tablets – Vertex)

REVIEW DATE: 02/07/2024; selected revision 04/10/2024 and 01/02/2025

OVERVIEW

Symdeko is indicated for the treatment of **cystic fibrosis** (CF) in patients ≥ 6 years of age who are homozygous for the F508del mutation or who have at least one mutation in the cystic fibrosis transmembrane conductance regulator (CFTR) gene that is responsive to tezacaftor/ivacaftor based on *in vitro* data and/or clinical evidence.¹

If the patient's genotype is unknown, an FDA-cleared CF mutation test should be used to detect the presence of a CFTR mutation followed by verification with bi-directional sequencing when recommended by the mutation test instructions for use. Table 1 lists the responsive CFTR mutations based on: 1) a clinical forced expiratory volume in 1 second (FEV₁) response and/or 2) *in vitro* data in Fischer rat thyroid cells, indicating that tezacaftor/ivacaftor increases chloride transport to $\geq 10\%$ of untreated normal over baseline. CFTR gene mutations that are not responsive to Kalydeco® (ivacaftor granule or tablet) alone are not expected to respond to Symdeko except for F508del homozygotes.

Table 1. List of CFTR Gene Mutations that Produce CFTR Protein and are Responsive to Symdeko.¹

Table 1 (continued). List of CFTR Gene Mutations that Produce CFTR Protein and are Responsive to Symdeko.¹

CFTR – Cystic fibrosis transmembrane conductance regulator; * A patient must have two copies of the F508del mutation or at least one copy of a responsive mutation presented in Table 1 to be indicated.

Guidelines

The most current treatment recommendations are the Standards of Care for CFTR variant-specific therapy for people with CF, from the European Cystic Fibrosis Society (2023).² However, the Standards do not reflect the currently approved age indications for Kalydeco® (ivacaftor tablets and oral granules) [≥ 1 months of age], Orkambi® [lumacaftor/ivacaftor tablets and oral granules] (≥ 1 year of age), or Trikafta® (elexacaftor/tezacaftor/ivacaftor; ivacaftor co-packaged tablets and granules) [≥ 2 years of age]. In general, Trikafta is recommended over other agents where indications overlap. The Standards recommend Trikafta in patients ≥ 6 years of age with CF who are homozygous or heterozygous for F508del. In patients with one or more responsive non-F508del variant, Kalydeco, Symdeko, or Trikafta are recommended. Kalydeco is recommended in patients ≥ 4 months of age with eligible CFTR gene variants. Orkambi is recommended for patients 2 to 5 years of age who are homozygous for F508del. Of note, the Standards state that after diagnosis, repeat sweat testing provides evidence of treatment effect on CFTR activity, but does not predict clinical response. The European Cystic Fibrosis Society Standards for establishing and maintaining health (2024) note that people with CF with eligible CFTR gene variants should be offered CFTR modulator therapy.⁵

According to the CF Foundation (2017), CF is diagnosed when an individual has both a clinical presentation of CF and evidence of CFTR dysfunction.^{3,4} Clinical presentation of CF includes a positive newborn screening, signs and/or symptoms of CF, and/or family history of CF. To establish a diagnosis of CF, sweat chloride tests should be considered first, then CFTR genetic analysis (CFTR genotype), and then CFTR physiologic tests (nasal potential difference [NPD] or intestinal current measurement [ICM]). However,

- i. Positive cystic fibrosis newborn screening test; OR
 - ii. Family of cystic fibrosis; OR
 - iii. Clinical presentation consistent with signs and symptoms of cystic fibrosis; AND
Note: Examples of clinical presentation of cystic fibrosis include but are not limited to meconium ileus, sino-pulmonary symptoms (e.g., persistent cough, wheezing, pulmonary function tests consistent with obstructive airway disease, excess sputum production), bronchiectasis, sinusitis, failure to thrive, pancreatic insufficiency.
- D) Patient has evidence of abnormal cystic fibrosis transmembrane conductance regulator function as demonstrated by at least ONE of the following (i, ii, or iii):
- i. Elevated sweat chloride test; OR
 - ii. Two cystic fibrosis-causing cystic fibrosis transmembrane conductance regulator mutations; OR
 - iii. Abnormal nasal potential difference; AND
- E) The medication is prescribed by or in consultation with a pulmonologist or a physician who specializes in the treatment of cystic fibrosis.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Symdeko is not recommended in the following situations:

1. **Cystic Fibrosis, Patient with Unknown Cystic Fibrosis Transmembrane Conductance Regulator Gene Mutation.** An FDA-cleared cystic fibrosis mutation test should be used to detect the presence of the cystic fibrosis transmembrane conductance regulator mutation prior to use of Symdeko.¹
80. **Combination Therapy with Other Cystic Fibrosis Transmembrane Conductance Regulator Modulator(s).** Symdeko contains ivacaftor, the active agent in Kalydeco® (tablets and oral granules) and part of Orkambi® (lumacaftor/ivacaftor tablets and oral granules) and Trikafta® (elexacaftor/tezacaftor/ivacaftor; ivacaftor co-packaged tablets and granules). Symdeko also contains tezacaftor, part of Trikafta.
Note: Examples of other cystic fibrosis transmembrane conductance regulator modulators are: Alyftrek™ (vanzacaftor/tezacaftor/deutivacaftor tablets), Kalydeco (ivacaftor tablets and oral granules), Orkambi (lumacaftor/ivacaftor tablets and oral granules), Trikafta (elexacaftor/tezacaftor/ivacaftor; ivacaftor co-packaged tablets and granules).
81. **Infertility.** Symdeko is indicated for the treatment of cystic fibrosis in a patient ≥ 6 years of age who is homozygous for the F508del mutation or who has at least one mutation in the cystic fibrosis transmembrane conductance regulator gene that is responsive to tezacaftor/ivacaftor based on *in vitro* data and/or clinical evidence.¹
Note: A patient with a diagnosis of cystic fibrosis should be reviewed using criteria for the FDA-approved indication, above.

4. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Cystic Fibrosis Transmembrane Conductance Regulator – Trikafta Prior Authorization Policy

- Trikafta® (elexacaftor/tezacaftor/ivacaftor tablets; ivacaftor tablets, co-packaged and elexacaftor/tezacaftor/ivacaftor oral granules; ivacaftor oral granules, co-packaged – Vertex)

REVIEW DATE: 04/10/2024; selected revision 01/02/2025

OVERVIEW

Trikafta is a combination of ivacaftor, a cystic fibrosis transmembrane regulator (CFTR) potentiator, tezacaftor, and elexacaftor. It is indicated for the **treatment of cystic fibrosis (CF)** in patients ≥ 2 years of age who:

- Have at least one F508del mutation in the CFTR gene; OR
- Have a mutation in the CFTR gene that is responsive to Trikafta based on *in vitro* data.¹

If the patient's genotype is unknown, an FDA-cleared CF mutation test should be used to confirm the presence of at least one indicated mutation. Table 1 lists responsive CFTR mutations based on clinical response, and/or *in vitro* data in Fischer Rat Thyroid cells or human bronchial endothelial cells, or based on extrapolation of efficacy.

Table 1. List of CFTR Gene Mutations that are Responsive to Trikafta.¹

Table 1 (continued). List of CFTR Gene Mutations that are Responsive to Trikafta.¹

CFTR – Cystic Fibrosis Transmembrane Conductance Regulator.

Guidelines

The most current treatment recommendations are the Standards of Care for CFTR variant-specific therapy for people with CF, from the European Cystic Fibrosis Society (2023).² However, the Standards do not reflect the currently approved age indications for Kalydeco® (ivacaftor tablets and oral granules) [≥ 1 months of age], Orkambi® [lumacaftor/ivacaftor tablets and oral granules] (≥ 1 year of age), or Trikafta (≥ 2 years of age). In general, Trikafta is recommended over other agents where indications overlap. The Standards recommend Trikafta in patients ≥ 6 years of age with CF who are homozygous or heterozygous for F508del. In patients with one or more responsive non-F508del variant, Kalydeco, Symdeko® (tezacaftor/ivacaftor and ivacaftor tablets), or Trikafta are recommended. Kalydeco is recommended in patients ≥ 4 months of age with eligible CFTR gene variants. Orkambi is recommended for patients 2 to 5 years of age who are homozygous for F508del. Of note, the Standards state that after diagnosis, repeat sweat testing provides evidence of treatment effect on CFTR activity, but does not predict clinical response. The European Cystic Fibrosis Society Standards for establishing and maintaining health (2024) note that people with CF with eligible CFTR gene variants should be offered CFTR modulator therapy.⁵

According to the CF Foundation (2017), CF is diagnosed when an individual has both a clinical presentation of CF and evidence of CFTR dysfunction.^{3,4} Clinical presentation of CF includes a positive newborn screening, signs and/or symptoms of CF, and/or family history of CF. To establish a diagnosis of CF, sweat chloride tests should be considered first, then CFTR genetic analysis (CFTR genotype), and then CFTR physiologic tests (nasal potential difference [NPD] or intestinal current measurement [ICM]). However, tests of CFTR function are not always done in this order. All individuals diagnosed with CF should have a sweat chloride test and CFTR genetic analysis performed.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

In a patient with a sweat chloride test ≥ 60 mmol/L, CF diagnosis is established and in patients with a sweat chloride test < 30 mmol/L, a diagnosis of CF is unlikely.^{3,4} Rarely, patients with a sweat chloride < 30 mmol/L may be considered to have CF if alternatives are excluded and other confirmatory tests (genetic and physiologic testing) support CF. In patients with a sweat chloride test of ≥ 30 to < 60 mmol/L, CFTR genetic analysis is undertaken. If the genetic analysis identifies two CF-causing CFTR mutations, CF is diagnosed, if no CFTR mutations are identified, a diagnosis of CF is unlikely. In patients with a CFTR genotype that is undefined or of varying clinical consequence, full gene CFTR sequencing (if not already performed) or CFTR physiologic testing is performed (NPD or ICM). If only one CFTR variant is identified on limited analysis, full gene CFTR sequencing should be performed. CF is possible if both alleles possess CF-causing, undefined, or mutation of varying clinical consequence mutations; CF is unlikely if only no CF-causing mutations are found. If results of the NPD or ICM show CFTR dysfunction, CF is diagnosed; when testing is unavailable or equivocal, the diagnosis of CF is not resolved, and when results of the physiologic testing show CFTR function is preserved, a diagnosis of CF is considered unlikely. It is recommended that patients with challenging diagnoses be evaluated at an accredited CF Foundation Care Center.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Trikafta. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Trikafta as well as the monitoring required for adverse events and long-term efficacy, approval requires Trikafta to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Trikafta is recommended in those who meet the following criteria:

FDA-Approved Indication

13. Cystic Fibrosis. Approve for 1 year if the patient meets ALL of the following (A, B, C, D, and E):

A) Patient is ≥ 2 years of age; AND

B) Patient has at least ONE of the following mutations in the cystic fibrosis conductance regulator gene that is considered to be a pathogenic or likely pathogenic variant: F508del, 3141del9, E822K, G1069R, L967S, R117L, S912L, 546insCTA, F191V, G1244E, L997F, R117P, S945L, A46D, F311del, G1249R, L1077P, R170H, S977F, A120T, F311L, G1349D, L1324P, R258G, S1159F, A234D, F508C, H139R, L1335P, R334L, S1159P, A349V, F508C;S1251N, H199Y, L1480P, R334Q, S1251N, A455E, H939R, M152V, R347H, S1255P, A554E, F575Y, H1054D, M265R, R347L, T338I, A1006E, F1016S, H1085P, M952I, R347P, T1036N, A1067T, F1052V, H1085R, M952T, R352Q, T1053I, D110E, F1074L, H1375P, M1101K, R352W, V201M, D110H, F1099L, I148T, P5L, R553Q, V232D, D192G, G27R, I175V, P67L, R668C, V456A, D443Y, G85E, I336K, P205S, R751L, V456F, D443Y;G576A;R668C, G126D, I502T, P574H, R792G, V562I, D579G, G178E, I601F, Q98R, R933G, V754M, D614G, G178R, I618T, Q237E, R1066H, V1153E, D836Y, G194R, I807M, Q237H, R1070Q, V1240G, D924N, G194V, I980K, Q359R, R1070W, V1293G, D979V, G314E, I1027T, Q1291R, R1162L, W361R, D1152H, G463V, I1139V, R31L, R1283M, W1098C, D1270N, G480C, I1269N, R74Q, R1283S, W1282R, E56K, G551D, I1366N, R74W, S13F, Y109N, E60K, G551S, K1060T, R74W;D1270N, S341P, Y161D, E92K, G576A, L15P, R74W;V201M, S364P, Y161S, E116K, G576A;R668C, L165S, R74W;V201M;D1270N, S492F,

C) Patient meets at least ONE of the following (i, ii, or iii):

- i.** Positive cystic fibrosis newborn screening test; OR
- ii.** Family of cystic fibrosis; OR
- iii.** Clinical presentation consistent with signs and symptoms of cystic fibrosis; AND

Note: Examples of clinical presentation of cystic fibrosis include but are not limited to meconium ileus, sino-pulmonary symptoms (e.g., persistent cough, wheezing, pulmonary function tests consistent with obstructive airway disease, excess sputum production), bronchiectasis, sinusitis, failure to thrive, pancreatic insufficiency.

D) Patient has evidence of abnormal cystic fibrosis transmembrane conductance regulator function as demonstrated by at least ONE of the following (i, ii, or iii):

- i.** Elevated sweat chloride test; OR
- ii.** Two cystic fibrosis-causing cystic fibrosis transmembrane conductance regulator mutations; OR
- iii.** Abnormal nasal potential difference; AND

E) The medication is prescribed by or in consultation with a pulmonologist or a physician who specializes in the treatment of cystic fibrosis.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Trikafta is not recommended in the following situations:

40. Cystic Fibrosis, Patient with Unknown Cystic Fibrosis Transmembrane Conductance Regulator Gene Mutation. An FDA-cleared cystic fibrosis mutation test should be used to detect the presence of at least one indicated mutation prior to use of Trikafta.¹

82. Combination Therapy with Other Cystic Fibrosis Transmembrane Conductance Regulator Modulator(s). Trikafta contains ivacaftor which is a component of Orkambi® (lumacaftor/ivacaftor tablets and oral granules), Kalydeco® (tablets and oral granules), and Symdeko® (tezacaftor/ivacaftor tablets; ivacaftor tablets). Tezacaftor, another component of Trikafta is also contained in Symdeko. Note: Examples of other cystic fibrosis transmembrane conductance regulator modulators are: Alyftrek™ (vanzacaftor/tezacaftor/deutivacaftor tablets), Kalydeco (ivacaftor tablets and oral granules), Orkambi (lumacaftor/ivacaftor tablets and oral granules), Symdeko (tezacaftor/ivacaftor; ivacaftor tablets).

3. Infertility. Trikafta is indicated for the treatment of cystic fibrosis in a patient ≥ 2 years of age who has at least one F508del mutation in the cystic fibrosis transmembrane conductance regulator gene, or has a mutation in the cystic fibrosis transmembrane conductance regulator gene that is responsive to Trikafta based on *in vitro* data.¹

PRIOR AUTHORIZATION POLICY

POLICY: Dermatology – Filsuvez Prior Authorization Policy

- Filsuvez® (birch triterpenes topical gel – Lichtenheldt GmbH/Chiesi)

REVIEW DATE: 01/21/2024

OVERVIEW

Filsuvez is indicated for the treatment of wounds associated with **dystrophic epidermolysis bullosa (DEB) and junctional epidermolysis bullosa (JEB) in patients ≥ 6 months of age.**¹

Filsuvez is a sterile botanical drug product for topical use and contains birch triterpenes in an oil base. Birch triterpenes is a botanical drug substance composed of a mixture of pentacyclic triterpenes. Filsuvez should be applied to cleansed wounds with wound dressing changes until the wound is healed. If a Filsuvez-treated wound becomes infected, treatment should be discontinued until the infection has resolved.

Disease Overview

DEB usually presents at birth and is divided into two major types depending on the pattern of inheritance: recessive DEB (RDEB) and dominant DEB (DDEB).⁶ All subtypes of DEB are caused by mutations in the gene coding COL7A1 leading to extreme skin fragility.^{4,6} The hallmark of DEB is scarring of blisters, both on the skin and on other mucosal surfaces.⁴

JEB is an autosomal recessive disorder characterized by skin blistering through the lamina lucida of the cutaneous basement membrane zone.⁴ The severity varies across the two major JEB subtypes, intermediate and severe, with severe disease causing death in the first 6 to 24 months of life. JEB is less common than DEB. Biallelic mutations in one of the three genes encoding the subunit chains of laminin 332 (LAMA3, LAMB3, LAMC2) can cause either JEB subtype, biallelic mutations of COL17A1 can also cause intermediate JEB and rarely severe JEB. Rare JEB subtypes are clinically and genetically heterogeneous and include several syndromic disorders. Wounds in JEB are characterized as having excessive granulation tissue, and frequently affect the face and occipital area, diaper area, and extremities.⁶ Wounds may heal with pigment changes or with scarring. Other features of JEB include extensive skin and mucous membrane involvement, failure to thrive and sepsis in severe subtypes, nail dystrophy and loss, and hair loss in intermediate and localized subtypes.

Clinical Efficacy

The efficacy of Filsuvez was evaluated in EASE, a Phase III, randomized, double-blind, placebo-controlled, multicenter, pivotal study in patients ≥ 21 days of age with inherited DEB or JEB ($n = 223$).^{2,3} Patients who had undergone stem cell transplant or gene therapy for the treatment of inherited epidermolysis bullosa (EB) were excluded. Additionally, patients with current and/or former malignancy including basal cell carcinomas and squamous cell carcinomas were ineligible to enroll.

The study consisted of a 90-day, double-blind, randomized, placebo-controlled treatment phase (published), followed by a 24-month, open-label, single-arm, follow-up phase (data unavailable).³ In the double-blind phase, patients were randomized 1:1 to Filsuvez or placebo vehicle gel, both with standard of care wound dressing applied at least once every 4 days (treatment with Filsuvez or placebo was applied at the same time as the wound dressing change). One EB target wound was assigned for each patient. The target wound involved loss of the epidermis; extension into the dermis was allowable. The target wound size was 10 cm² to 50 cm² in surface area and the age of the target wound was ≥ 21 days but < 9 months according to the

01/21/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

patient's report. For the assessment of wound closure and re-epithelization, the investigator photographed the target wound and all other wounds that matched target wound criteria with a system that measures accurately, precisely, and reliably to provide high quality imaging and standardized documentation. Post-treatment assessments were made within 1 week of wound closure to determine the durability of healing.

The median patient age was 12 years.² The median wound size was 15.6 cm² and the median wound age was 35.5 days. Most patients had RDEB (78.5%); 9.0% of patients had DDEB and 11.0% of patients had JEB. In the DDEB subgroup, there was an imbalance between patients receiving Filsuvez (n = 6) and placebo (n = 14). Among patients with RDEB, more than 55% had generalized-severe RDEB.

At Day 45 (± 7 days) 41.3% vs. 28.9% of patients receiving Filsuvez vs. placebo, respectively, had complete wound closure (P = 0.013). However, a subgroup analysis by EB subtype demonstrated that patients with RDEB (Filsuvez n = 91 and placebo n = 84) were the only subgroup to have a statistically significant benefit from Filsuvez; complete target wound closure by Day 45 was achieved in 44.0% of wounds treated with Filsuvez vs. 26.2% of placebo-treated wounds (relative risk 1.72; 95% CI: 1.14, 2.59; P = 0.008). In patients with JEB (n = 26) and DDEB (n = 20), differences between Filsuvez and placebo groups did not reach statistical significance (18.6% vs. 26.7%, respectively, in JEB and 50% vs. 50%, respectively, in DDEB), although numbers were small. At Day 90, the difference in time to first target wound closure over was not significantly different between the Filsuvez and placebo arms (50.5% vs. 43.9%, respectively). Differences in total wound burden were not statistically different between Filsuvez and placebo. There were improvements in the Itch Man Scale (patients ≥ 4 years of age) with both Filsuvez and placebo (a significant difference with Filsuvez was only observed at Day 60).² There was a statistically significant reduction in procedural pain with Filsuvez vs. placebo at Days 14 and 90 only, not at other timepoints (Day 30, Day 45, and Day 60). In an analysis of dressing change frequency, patients treated with Filsuvez had a reduced requirement for daily dressing changes vs. placebo; at Day 90 this equated to one less dressing change every 2 weeks with Filsuvez vs. no change with placebo.

Guidelines

Filsuvez is not addressed in available guidelines. According to a position statement by the **European Reference Network for Rare Skin Diseases** (2021), wound care is the cornerstone of treatment for patients with EB.⁵ Careful and complete skin and wound assessment should be undertaken regularly, at least every 6 months. The healing rate of chronic wounds should be closely monitored, by checking wound edges.

The diagnosis of EB is based on a combination of clinical features, family , and laboratory findings.⁵ Laboratory techniques include immunofluorescence mapping, transmission electron microscopy, and molecular genetic testing. Whenever possible, laboratory diagnosis should be performed in a specialized EB center. Genetic testing is the gold standard for the diagnosis of EB, since it provides a definitive diagnosis and classification of the major EB type and in many cases the subtype.

An **international consensus best practice guideline** on skin and wound care in EB [2017] notes that EB is a lifelong disease that requires specialist intervention and consideration to minimize complications and improve quality of life.⁶ Management should take place in a specialized center by a multi-disciplinary team, ideally. Definitive diagnosis is most commonly made from analysis of a skin biopsy using positive immunofluorescence, antigenic mapping, and transmission electron microscopy. These key diagnostic tools help confirm diagnosis and indicate the particular subtype of EB. Due to the rarity of expertise and facilities, diagnosis is generally made using immunofluorescence and antigen mapping. Some laboratories are moving towards molecular diagnosis from exome sequencing of a panel of known skin fragility genes. Experienced clinicians can often make a provisional diagnosis on clinical observations, but a definitive diagnosis will always be required.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Filsuvez. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Filsuvez as well as the monitoring required for adverse events and long-term efficacy, approval requires Filsuvez to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Documentation: Documentation is required for use of Filsuvez as noted in the criteria as **[documentation required]**. Documentation may include, but is not limited to, chart notes, prescription claims records, prescription receipts, and/or other information.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Filsuvez is recommended in those who meet the following criteria:

FDA-Approved Indication

14. Dystrophic Epidermolysis Bullosa. Approve for the duration outlined below if the patient meets ONE of the following (A or B):

Note: For new wound(s) the patient is directed to Initial Therapy criteria. If the patient is continuing to treat the same wound(s) the patient is directed to criteria for Patient Currently Receiving Filsuvez on Previously Treated Wound(s).

A) Initial Therapy: Approve for 3 months if the patient meets the following (i, ii, and iii):

- i. Patient is ≥ 6 months of age; AND
- ii. Patient meets ALL of the following (a, b, and c):
 - a) Patient has at least one clinical feature of dystrophic epidermolysis bullosa **[documentation required]**; AND
Note: Examples of clinical features of dystrophic epidermolysis bullosa include but are not limited to blistering, wounds, and scarring.
 - b) Patient has one or more open wound(s) that will be treated (i.e., “target wound[s]”); AND
 - c) Target wound(s) meet the following, according to the prescriber [(1), (2), (3), and (4)]:
 - (1) Target wound(s) is clean in appearance and does not appear to be infected; AND
 - (2) Target wound(s) is 10 cm² to 50 cm²; AND
 - (3) Target wound(s) is ≥ 21 days and < 9 months old; AND
 - (4) Squamous cell and/or basal cell carcinoma has been ruled out for the target wound(s).
- iii. The medication is prescribed by or in consultation with a dermatologist or wound care specialist.

B) Patient is Currently Receiving Filsuvez on Previously Treated Wound(s): Approve for 3 months if the patient meets ALL of the following (i, ii, and iii):

Note: If the patient is treating a new wound(s) not previously treated with Filsuvez or a reopened recurrent wound(s), then refer to Initial Therapy criteria above.

- i. According to the prescriber, the target wound(s) remains open; AND
- ii. According to the prescriber, the target wound(s) has decreased in size from baseline; AND
- iii. The medication is prescribed by or in consultation with a dermatologist or wound care specialist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Filsuvez is not recommended in the following situations:

41. **Combination use with Vyjuvek (beremagene geperpavec-svdt topical gel).** Combination use of Vyjuvek and Filsuvez have not been studied. Patients who had undergone gene therapy for the treatment of inherited EB were excluded from the pivotal EASE trial with Filsuvez.²
42. **Junctional Epidermolysis Bullosa (JEB).** Efficacy has not proven to be better than placebo. In the pivotal EASE trial, patients with JEB comprised 11% of the total population (n = 26).² At Day 45 ($\pm$ 7 days) complete wound closure in patients with JEB was greater in patients who received placebo vs. Filsuvez (26.7% vs. 18.6%).
43. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Dermatology – Gene Therapy – Vyjuvek Prior Authorization Policy

- Vyjuvek™ (beremagene geperpavec-svdt topical gel – Krystal Biotech)

REVIEW DATE: 06/26/2024

OVERVIEW

Vyjuvek, a herpes-simplex virus type-1 (HSV-1) vector-based gene therapy, is indicated for the treatment of wounds with **dystrophic epidermolysis bullosa** (DEB) with mutation(s) in the collagen type VII alpha 1 chain (COL7A1) gene in patients ≥ 6 months of age.¹

Vyjuvek is a live, replication defective HSV-1-based vector that has been genetically modified to express the human type VII collagen (COL7) protein.¹ Mutation(s) in the COL7A1 gene result in reduced or absent levels of biologically active COL7 in patients with DEB. COL7 protein is a crucial component of anchoring fibrils that are essential for maintaining skin integrity. Application of Vyjuvek to wounds results in transcription of the encoded human COL7A1 and production and secretion of COL7 by the cell in its mature form. The COL7 molecules form anchoring fibrils that hold the epidermis and dermis together.

Disease Overview

DEB usually presents at birth and is divided into two major types depending on the pattern of inheritance: recessive DEB (RDEB) and dominant DEB (DDEB).⁶ All subtypes of DEB are caused by mutations in the gene coding COL7A1 leading to extreme skin fragility.^{4,6} The hallmark of DEB is scarring of blisters, both on the skin and on other mucosal surfaces.⁴

Clinical Efficacy

GEM-3, a Phase III, double-blind, placebo-controlled, inpatient randomized, pivotal study, assigned patients with DEB to treat two similarly sized wounds; one with Vyjuvek and one with placebo for 26 weeks (N = 31).² Eligible patients were ≥ 6 months of age presenting with a clinical diagnosis of DEB, characterized by blistering, wounds, and scarring and confirmed by genetic testing including COL7A1. The appearance of the wounds was to be clean with adequate granulation tissue, excellent vascularization, and to not appear infected. Patients receiving immunotherapy, chemotherapy, or other investigational products were not included. In addition, wound sites with current evidence or a history of squamous-cell carcinoma or active infection were excluded as sites for Vyjuvek (or placebo) application. Vyjuvek or placebo was applied only to open wounds. Wounds were evaluated weekly to determine continued application of Vyjuvek or placebo. If a healed wound reopened, application was resumed; if the wound remained closed, application was omitted. All but one patient had the recessive DEB genotype. At Month 6, significantly more Vyjuvek- vs. placebo-treated wounds were completely healed (67% vs. 22%, respectively; P = 0.002) [primary endpoint]. Similar results were observed at Month 3 favoring Vyjuvek vs. placebo for complete wound healing (71% vs. 20%, respectively; P < 0.001). Durability (complete wound healing at both Months 3 and 6) was seen in 50% vs. 7% of Vyjuvek- vs. placebo-treated wounds, respectively (difference 43%; 95% confidence interval: 23%, 63%). One patient had a chronic secondary wound of the back measuring > 100 cm² that had been open for > 10 years. Following Vyjuvek treatment, the patient was able to resume activities of daily living, including showering, which had not previously been possible due to the open nature of the wound.

Guidelines

Vyjuvek is not addressed in available guidelines. According to a position statement by the **European Reference Network for Rare Skin Diseases** (2021), wound care is the cornerstone of treatment for patients with DEB.⁵ Careful and complete skin and wound assessment should be undertaken regularly, at least every 6 months. The healing rate of chronic wounds should be closely monitored, by checking wound edges.

The diagnosis of DEB is based on a combination of clinical features, family , and laboratory findings.⁵ Laboratory techniques include immunofluorescence mapping, transmission electron microscopy, and molecular genetic testing. Whenever possible, laboratory diagnosis should be performed in a specialized DEB center. Genetic testing is the gold standard for the diagnosis of DEB, since it provides a definitive diagnosis and classification of the major DEB type and in many cases the subtype.

An **international consensus best practice guideline** on skin and wound care in epidermolysis bullosa (EB) [2017] notes that EB is a lifelong disease that requires specialist intervention and consideration to minimize complications and improve quality of life.⁶ Management should take place in a specialized center by a multi-disciplinary team, ideally. Definitive diagnosis is most commonly made from analysis of a skin biopsy using positive immunofluorescence, antigenic mapping, and transmission electron microscopy. These key diagnostic tools help confirm diagnosis and indicate the particular subtype of EB. Due to the rarity of expertise and facilities, diagnosis is generally made using immunofluorescence and antigen mapping. Some laboratories are moving towards molecular diagnosis from exome sequencing of a panel of known skin fragility genes. Experienced clinicians can often make a provisional diagnosis on clinical observations, but a definitive diagnosis will always be required.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Vyjuvek. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Vyjuvek as well as the monitoring required for adverse events and long-term efficacy, approval requires Vyjuvek to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Documentation: Documentation is required for use of Vyjuvek as noted in the criteria as **[documentation required]**. Documentation may include, but is not limited to, chart notes, prescription claims records, prescription receipts, and/or other information.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Vyjuvek is recommended in those who meet the following criteria:

FDA-Approved Indication

15. Dystrophic Epidermolysis Bullosa. Approve for the duration outlined below if the patient meets ONE of the following (A or B):

Note: For new wound(s) the patient is directed to Initial Therapy criteria. If the patient is continuing to treat the same wound(s) the patient is directed to criteria for Patient Currently Receiving Vyjuvek on Previously Treated Wound(s).

06/26/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- A) **Initial Therapy:** Approve for 6 months if the patient meets ALL of the following (i, ii, iii, and iv):
- i. Patient is ≥ 6 months of age; AND
 - ii. The diagnosis is confirmed by genetic testing showing a pathogenic mutation in the collagen type VII alpha 1 chain (COL7A1) gene **[documentation required]**; AND
 - iii. Patient meets ALL of the following (a, b, and c):
 - a) Patient has at least one clinical feature of dystrophic epidermolysis bullosa **[documentation required]**; AND
Note: Examples of clinical features of dystrophic epidermolysis bullosa include but are not limited to blistering, wounds, and scarring.
 - b) Patient has one or more open wound(s) that will be treated (i.e., “target wound[s]”); AND
 - c) Target wound(s) meet ALL of the following, according to the prescriber [(1), (2), and (3)]:
 - (1) Target wound(s) is clean in appearance and does not appear to be infected; AND
 - (2) Target wound(s) has adequate granulation tissue and vascularization; AND
 - (3) Squamous cell carcinoma has been ruled out for the target wound(s); AND
 - iv. The medication is prescribed by or in consultation with a dermatologist or wound care specialist.
- B) **Patient is Currently Receiving Vyjuvek on Previously Treated Wound(s):** Approve for 6 months if the patient meets ALL of the following (i, ii, and iii):
- Note: If the patient is treating a new wound(s) not previously treated with Vyjuvek or a reopened recurrent wound(s), then refer to Initial Therapy criteria above.
- i. According to the prescriber, the target wound(s) remains open; AND
 - ii. According to the prescriber, the target wound(s) has decreased in size from baseline; AND
 - iii. The medication is prescribed by or in consultation with a dermatologist or wound care specialist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Vyjuvek is not recommended in the following situations:

44. **Combination use with Filsuvez (birch triterpenes topical gel).** Combination use of Vyjuvek and Filsuvez have not been studied.⁷
45. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Dermatology – Hyftor Prior Authorization Policy

- Hyftor® (sirolimus 0.2% topical gel – Nobelpharma)

REVIEW DATE: 06/05/2024

OVERVIEW

Hyftor, a topical mammalian target of rapamycin inhibitor immunosuppressant, is indicated for the treatment of **facial angiofibroma associated with tuberous sclerosis** in patients ≥ 6 years of age.¹

Disease Overview

Tuberous sclerosis complex is an autosomal dominant genetic disorder caused by mutations in two genes, tuberous sclerosis 1 and tuberous sclerosis 2.²⁻⁴ The incidence rate is approximately one in 6,000 to 10,000 births. It is characterized by non-cancerous (benign) tumors that grow in the brain, as well as in other vital organs such as the kidneys, heart, eyes, lungs, and skin. It can also impact the central nervous system causing seizures, impaired intellectual development, autism, and behavioral issues. The disease has great variability but can occur when patients are very young (around 1 year of age). Most patients (up to 80%) experience various skin conditions due to the disease such as angiofibromas, hypomelanotic macules, and cephalic plaques. Angiofibromas in the face usually appear in young children and gradually proliferate thereafter. This manifestation can be serious as well as disfiguring.

Clinical Efficacy

The efficacy of Hyftor for its approved use was evaluated in one Phase III, randomized, double-blind, vehicle-controlled, multicenter pivotal study conducted in Japan involving 62 patients who were 6 years of age and older.^{1,2} The trial enrolled patients with tuberous sclerosis complex who had three or more facial angiofibromas that were at least 2 mm in diameter with redness present in each. Patients also had a definitive diagnosis of tuberous sclerosis complex. Use of Hyftor reduced the lesion size and redness of the facial angiofibromas after 12 weeks of use compared with vehicle.^{1,2} The assessment at 4 weeks after discontinuation of Hyftor suggests that continuation of therapy is required for benefit.² It is recommended that if symptoms do not improve within 12 weeks of Hyftor treatment, the need for continuing Hyftor should be reevaluated.¹

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Hyftor. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Hyftor as well as the monitoring required for adverse events and long-term efficacy, approval requires Hyftor to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Hyftor is recommended in those who meet the following criteria:

FDA-Approved Indication

06/05/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

16. Facial Angiofibroma Associated with Tuberous Sclerosis. Approve for the duration noted below if the patient meets ONE of the following (A or B):

A) Initial Therapy. Approve for 3 months if the patient meets ALL of the following (i, ii, iii, and iv):

- i. Patient is ≥ 6 years of age; AND
- ii. Patient has a definitive diagnosis of tuberous sclerosis complex by meeting ONE of the following (a or b):
 - a) There is identification of a pathogenic variant in the tuberous sclerosis complex 1 (*TSC1*) gene or tuberous sclerosis complex 2 (*TSC2*) gene by genetic testing; OR
 - b) According to the prescriber, clinical diagnostic criteria suggest a definitive diagnosis of tuberous sclerosis complex by meeting either two major features or one major feature with two minor features; AND
- iii. Patient has three or more facial angiofibromas that are at least 2 mm in diameter with redness in each; AND
- iv. The medication is prescribed by or in consultation with a dermatologist or a physician who specializes in the management of patients with tuberous sclerosis complex; OR

Note: Major feature criteria involve angiofibroma (three or more) or fibrous cephalic plaque; angiomyolipomas (two or more); cardiac rhabdomyoma; hypomelanotic macules (three or more; at least 5 mm in diameter); lymphangiomyomatosis; multiple cortical tubers and/or radial migration lines; multiple retinal hamartomas; Shagreen patch; subependymal giant cell astrocytoma; subependymal nodule (two or more); or ungula fibromas (two or more). Minor feature criteria involve “confetti” skin lesions; dental enamel pits (three or more); intraoral fibromas (two or more); multiple renal cysts; nonrenal hamartomas; retinal achromic patch; and sclerotic bone lesions.

B) Patient Currently Receiving Hyftor. Approve for 1 year if the patient meets ALL of the following (i, ii, iii, and iv):

- i. Patient is ≥ 6 years of age; AND
- ii. Patient has a definitive diagnosis of tuberous sclerosis complex by meeting ONE of the following (a or b):
 - a) There is identification of a pathogenic variant in the tuberous sclerosis complex 1 (*TSC1*) gene or tuberous sclerosis complex 2 (*TSC2*) gene by genetic testing; OR
 - b) According to the prescriber, clinical diagnostic criteria suggest a definitive diagnosis of tuberous sclerosis complex by meeting either two major features or one major feature with two minor features; AND
- iii. Patient has responded to Hyftor as evidenced by a reduction in the size and/or redness of the facial angiofibromas, as determined by the prescriber; AND
- iv. The medication is prescribed by or in consultation with a dermatologist or a physician who specializes in the management of patients with tuberous sclerosis complex.

Note: Major feature criteria involve angiofibroma (three or more) or fibrous cephalic plaque; angiomyolipomas (two or more); cardiac rhabdomyoma; hypomelanotic macules (three or more; at least 5 mm in diameter); lymphangiomyomatosis; multiple cortical tubers and/or radial migration lines; multiple retinal hamartomas; Shagreen patch; subependymal giant cell astrocytoma; subependymal nodule (two or more); or ungula fibromas (two or more). Minor feature criteria involve “confetti” skin lesions; dental enamel pits (three or more); intraoral fibromas (two or more); multiple renal cysts; nonrenal hamartomas; retinal achromic patch; and sclerotic bone lesions.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Hyftor is not recommended in the following situations:

06/05/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

46. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Dermatology – Opzelura Prior Authorization Policy

- Opzelura® (ruxolitinib 1.5% cream – Incyte)

REVIEW DATE: 09/04/2024

OVERVIEW

Opzelura, a Janus kinase (JAK) inhibitor, is indicated for the following uses:¹

- **Atopic dermatitis**, for the topical short-term and non-continuous treatment of mild to moderate disease in patients ≥ 12 years of age whose disease is not adequately controlled with topical prescription therapies or when those therapies are not advisable.
- **Nonsegmental vitiligo**, for the topical treatment of patients ≥ 12 years of age.

Limitation of Use: Use of Opzelura in combination with therapeutic biologics, other JAK inhibitors, or potent immunosuppressants such as azathioprine or cyclosporine is not recommended.

For atopic dermatitis, Opzelura is applied twice daily to affected areas of up to 20% body surface area (BSA). Patients should stop using Opzelura when signs and symptoms of atopic dermatitis (e.g., itch, rash, and redness) resolve. If signs and symptoms do not improve within 8 weeks, patients should be re-evaluated by their healthcare provider.

For vitiligo, Opzelura is applied twice daily to affected areas of up to 10% BSA.¹ Patients may require more than 24 weeks of treatment to achieve a satisfactory response. If the patient does not find the repigmentation meaningful after 24 weeks of therapy, the patient should be re-evaluated by their healthcare provider.

Clinical Efficacy

Atopic Dermatitis

Two pivotal Opzelura studies enrolled patients ≥ 12 years of age with a diagnosis of atopic dermatitis present for ≥ 2 years, affecting 3% to 20% of their BSA.^{1,2} Patients were also required to have an Investigator's Global Assessment (IGA) score of 2 or 3. While prior treatment was not a requirement for study enrollment, 90% of patients had received prior therapies for atopic dermatitis, including low-, medium-, and high-potency topical corticosteroids (49.6%, 42.4%, and 32.7% of patients, respectively), as well as topical calcineurin inhibitors (e.g., tacrolimus 0.03% and 0.1% ointment and pimecrolimus 1% cream [Elidel®, generic]) [21.5% of patients]. At Week 8, Opzelura cream was found to be more effective in achieving IGA treatment success, defined as an IGA score of 0 (clear) or 1 (almost clear) with a ≥ 2 -grade improvement from baseline. A third, non-pivotal, Phase II trial of Opzelura cream in a similar patient population included a triamcinolone acetonide 0.1% cream comparator arm.³ At Week 4, Opzelura 1.5% cream produced greater improvement in the Eczema Area and Severity Index score from baseline; however, the treatment difference vs. triamcinolone was not statistically significant.

Vitiligo

One Phase III Opzelura study enrolled patients ≥ 12 years of age with a diagnosis of non-segmental vitiligo and depigmented areas covering $\leq 10\%$ of their BSA.⁴ While prior treatment was not a requirement for study enrollment, 61% of patients had received prior topical therapies for vitiligo, including topical corticosteroids and topical calcineurin inhibitors. Efficacy was evaluated at Week 24.

Guidelines

09/04/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Atopic Dermatitis Guidelines

In general, the American Academy of Dermatology Guidelines of Care for the Management of Atopic Dermatitis (2014) recommends moisturizers/emollients as first-line therapy, followed by topical corticosteroids, when appropriate.⁵ Topical calcineurin inhibitors are recommended for the treatment of atopic dermatitis, particularly when use of topical corticosteroids is not appropriate due to safety concerns (e.g., young infants, treatment of sensitive areas such as the face, eyelids, or genitalia). Opzelura is recommended for the treatment of patients with mild to moderate atopic dermatitis. However, Opzelura should not be used on more than 20% of the patient's BSA to avoid potential adverse events.

Vitiligo Guidelines

Guidelines from the International Vitiligo Task Force (2023) recommend topical corticosteroids, topical calcineurin inhibitors, and Opzelura as treatment options in patients with vitiligo.⁶ Most of the studies to support the use of topical corticosteroids used potent to very potent corticosteroids applied topically daily for 3 to 6 months. Intermittent/alternating treatment schemes have been found to reduce adverse effects from topical corticosteroids and may enable longer treatment periods. Topical corticosteroids should be used with caution on the eyelids, axilla, and inguinal regions. Topical calcineurin inhibitors are often prescribed initially for up to 6 months. The guidelines note that topical corticosteroids and topical calcineurin inhibitors have not been found to be different in terms of efficacy; however, there are safety differences. These therapies may be used in combination. The guidelines do not compare the efficacy of Opzelura with that of the other topical therapies.

Safety

Opzelura carries a Boxed Warning regarding the risk of serious infections, mortality, malignancy and lymphoproliferative disorders, major adverse cardiac events, and thrombosis.¹ Other Warnings and Precautions include thrombocytopenia, anemia, neutropenia, and lipid elevations. Based on these risks, critical evaluation and monitoring of certain patients are recommended in the Opzelura prescribing information.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Opzelura cream. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Opzelura cream as well as the monitoring required for adverse events and long-term efficacy, approval requires Opzelura cream to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Opzelura cream is recommended in those who meet one of the following criteria:

FDA-Approved Indications

17. Atopic Dermatitis. Approve for 8 weeks if the patient meets ALL of the following (A, B, C, D, E, and F):

- A) Patient is ≥ 12 years of age; AND
- B) According to the prescriber, patient has mild to moderate atopic dermatitis; AND
- C) Patient has atopic dermatitis involvement estimated to affect $\leq 20\%$ of the body surface area; AND
- D) Patient meets ONE of the following (i or ii):
 - i. Patient meets ALL of the following (a, b, and c):
 - a) Patient has tried at least one medium-, medium-high, high-, and/or super-high-potency prescription topical corticosteroid; AND
Note: Concomitant use of a topical corticosteroid with a topical calcineurin inhibitor would meet the requirement.
 - b) This topical corticosteroid was applied daily for at least 28 consecutive days; AND
 - c) According to the prescriber, inadequate efficacy was demonstrated with this topical corticosteroid therapy; OR
 - ii. Patient is treating atopic dermatitis affecting one of the following areas: face, eyes/eyelids, skin folds, and/or genitalia; AND
- E) Patients meets ALL of the following (i, ii, and iii):
 - i. Patient has tried at least one topical calcineurin inhibitor; AND
Note: Examples of topical calcineurin inhibitors include tacrolimus ointment (Protopic, generic) and pimecrolimus cream (Elidel, generic). Concomitant use of a topical calcineurin inhibitor with a topical corticosteroid would meet the requirement.
 - ii. This topical calcineurin inhibitor was applied daily for at least 28 consecutive days; AND
 - iii. According to the prescriber, inadequate efficacy was demonstrated with this topical calcineurin inhibitor; AND
- F) The medication is prescribed by or in consultation with an allergist, immunologist, or dermatologist.

18. Vitiligo. Approve for 6 months if the patient meets ALL of the following (A, B, C, D, E, and F):

- A) Patient is ≥ 12 years of age; AND
- B) Patient has nonsegmental vitiligo; AND
- C) Patient has vitiligo involvement estimated to affect $\leq 10\%$ of the body surface area; AND
- D) Patient meets ONE of the following (i or ii):
 - i. Patient meets ALL of the following (a, b, and c):
 - a) Patient has tried at least one high-, and/or super-high-potency prescription topical corticosteroid; AND
Note: Concomitant use of a topical corticosteroid with a topical calcineurin inhibitor would meet the requirement.
 - b) The duration of this topical corticosteroid therapy was at least 12 weeks; AND
Note: Intermittent or continuous use of a topical corticosteroid for at least 12 weeks would meet the requirement.
 - c) According to the prescriber, inadequate efficacy was demonstrated with this topical corticosteroid therapy; OR
 - ii. Patient is treating vitiligo affecting one of the following areas: face, eyes/eyelids, skin folds, and/or genitalia; AND
- E) Patients meets ALL of the following (i, ii, and iii):
 - i. Patient has tried at least one topical calcineurin inhibitor; AND

- Note: Examples of topical calcineurin inhibitors include tacrolimus ointment (Protopic, generic) and pimecrolimus cream (Elidel, generic). Concomitant use of a topical calcineurin inhibitor with a topical corticosteroid would meet the requirement.
- ii. This topical calcineurin inhibitor was applied daily for at least 12 weeks; AND
 - iii. According to the prescriber, inadequate efficacy was demonstrated with this topical calcineurin inhibitor; AND
- F) The medication is prescribed by or in consultation with a dermatologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Opzelura cream is not recommended in the following situations:

- 47. Concurrent Use with a Biologic or with other JAK inhibitors.** Use of Opzelura in combination with therapeutic biologics or other JAK inhibitors is not recommended (see Appendix for examples).¹ Use of biologics or other JAK inhibitors was prohibited during the Opzelura pivotal studies.² There are no data evaluating combination use of Opzelura with these therapies; therefore, safety and efficacy of these combinations are unknown.
- 48. Concurrent use with Other Potent Immunosuppressants** (e.g., azathioprine, cyclosporine). Use of Opzelura in combination with potent immunosuppressants is not recommended.¹ Use of systemic immunosuppressants was prohibited during the Opzelura pivotal studies.² There are no data evaluating combination of Opzelura with these therapies; therefore, safety and efficacy of these combinations are unknown.
- 49. Alopecia.** Opzelura is not indicated for the treatment of alopecia.¹ A Phase II study involving patients with alopecia areata did not find any significant improvement in hair regrowth with Opzelura 1.5% cream compared with vehicle.⁷ Additional data are needed to establish the efficacy and safety of Opzelura in patients with alopecia.
- 50. Plaque Psoriasis.** Opzelura is not indicated for the treatment of plaque psoriasis.¹ There are very limited Phase II data regarding the use of Opzelura in patients with plaque psoriasis.^{8,9} Additional data are needed to establish the efficacy and safety of Opzelura in patients with plaque psoriasis.
- 51.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Desmopressin Products – Nocdurna Prior Authorization Policy

- Nocdurna® (desmopressin acetate sublingual tablets [27.7 mcg and 55.3 mcg] – Ferring)

REVIEW DATE: 12/11/2024

OVERVIEW

Nocdurna, a vasopressin analog, is indicated for the treatment of **nocturia due to nocturnal polyuria** in adults who awaken at least two times per night to void.¹ Before initiating therapy, it is recommended that the diagnosis of nocturnal polyuria has been confirmed with a 24-hour urine collection.

Disease Overview

Nocturnal polyuria is defined as nocturnal urine volume exceeding 33% of the total 24-hour urine volume in patients ≥ 65 years of age or exceeding 20% of 24-hour urine volume in younger patients.² Nocturnal polyuria may improve via lifestyle and behavior modifications, which should be implemented prior to pharmacotherapy.³ Such modifications include minimizing fluid intake before bed (particularly caffeine and alcohol), restriction of total fluid consumption, emptying the bladder before bed, increasing exercise and fitness levels, earlier dosing of medications such as diuretics, and elevating the legs above heart level for a few hours before going to bed (for patients with peripheral edema).

Safety

Nocdurna has a Boxed Warning regarding hyponatremia.¹ Use of Nocdurna is contraindicated in patients at increased risk of severe hyponatremia such as patients with excessive fluid intake, illness that may cause fluid or electrolyte imbalances, and in patients using loop diuretics or systemic or inhaled glucocorticoids. It is recommended to check serum sodium concentrations prior to initiating or resuming Nocdurna and throughout treatment. If hyponatremia occurs, Nocdurna may need to be temporarily or permanently discontinued. Nocdurna is contraindicated in patients with hyponatremia or among those with a history of hyponatremia.¹ Also, patients with polydipsia should not use Nocdurna. Do not administer Nocdurna concomitantly with loop diuretics or with systemic or inhaled glucocorticoids. Patients with renal impairment with an estimated glomerular filtration rate < 50 mL/min/1.73 m² should not use Nocdurna. Those with known or suspected syndrome of inappropriate antidiuretic hormone secretion should not use Nocdurna. Do not utilize Nocdurna during illnesses that may cause fluid or electrolyte imbalance, such as gastroenteritis, salt-wasting nephropathies, or systemic infection. Nocdurna is contraindicated in patients with heart failure or among those with uncontrolled hypertension because the fluid retention in these conditions increases the risk of worsening the underlying condition. Also, Nocdurna is not recommended in patients at risk for increased intracranial pressure or those with a of urinary retention. Trials involving Nocdurna have not included pediatric patients.

Guidelines

A consensus statement on the diagnosis and treatment of nocturia was published by the International Continence Society in 2019.² There was consensus that fluid restriction should be advised for all desmopressin-treated patients. Newer desmopressin formulations, including Nocdurna and Noctiva® (desmopressin acetate nasal spray), are generally regarded as low-dose desmopressin products. Low-dose formulations are appropriate in the absence of contraindications to desmopressin therapy.

12/11/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Nocdurna. All approvals are provided for the duration noted below. Due to the specialized skills required for evaluation and diagnosis of patients treated with Nocdurna, as well as the monitoring required for adverse events and long-term efficacy, approval requires Nocdurna to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Nocdurna is recommended in those who meet the following criteria:

FDA-Approved Indication

- 31. Nocturia due to Nocturnal Polyuria.** Approve for 1 year if the patient meets ALL of the following (A, B, C, D, E, F, and G):
- G)** Patient is ≥ 18 years of age; AND
 - H)** The diagnosis of nocturnal polyuria has been confirmed with a 24-hour urine collection before treatment initiation AND the patient meets ONE of the following (i or ii):
 - i.** Patient is < 65 years of age: The nocturnal urine volume exceeds 20% of the total 24-hour urine volume; OR
 - ii.** Patient is ≥ 65 years of age: The nocturnal urine volume exceeds 33% of the total 24-hour urine volume; AND
 - I)** Prior to desmopressin therapy, patient awakens at least two times per night to void; AND
 - J)** Patient has serum sodium concentrations within the normal range (135 to 145 mmol/L); AND
 - K)** Prescriber has verified that the patient does not have the following conditions/circumstances in which use of Nocdurna is not recommended (i, ii, iii, iv, v, or vi):
 - i.** Currently receiving loop diuretics; OR
Note: Examples of loop diuretics include furosemide, torsemide, bumetanide.
 - ii.** Currently receiving systemic or inhaled glucocorticoids; OR
 - iii.** Renal impairment with an estimated glomerular filtration rate < 50 mL/min/1.73 m²; OR
 - iv.** Heart failure; OR
 - v.** Polydipsia; OR
 - vi.** Known or suspected syndrome of inappropriate antidiuretic hormone secretion; AND
 - L)** Patient has tried non-pharmacologic techniques or lifestyle interventions to manage the nocturia; AND
Note: Examples of non-pharmacologic techniques for nocturia include nighttime fluid restriction, avoidance of caffeine and alcohol, earlier timing of medications, leg elevation, or use of compression stockings.
 - M)** The medication is prescribed by or in consultation with a nephrologist, urologist, geriatrician, or endocrinologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Nocdurna is not recommended in the following situations:

- 83.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION WITH STEP THERAPY POLICY

- POLICY:** Desmopressin Products – Noctiva Prior Authorization with Step Therapy Policy
- Noctiva™ (desmopressin acetate nasal spray [0.83 mcg/0.1 mL and 1.66 mcg/0.1 mL] – Avadel)

REVIEW DATE: 12/11/2024

OVERVIEW

Noctiva, a vasopressin analog, is indicated for the treatment of **nocturia due to nocturnal polyuria** in adults who awaken at least two times per night to void.¹ Before initiating therapy, it is recommended that the diagnosis of nocturnal polyuria has been confirmed with a 24-hour urine collection. A limitation of use is that the agent has not been studied in patients < 50 years of age.

Disease Overview

Nocturnal polyuria is defined as nocturnal urine volume exceeding 33% of the total 24-hour urine volume in patients ≥ 65 years of age or exceeding 20% of 24-hour urine volume in younger patients.² Nocturnal polyuria may improve via lifestyle and behavior modifications, which should be implemented prior to pharmacotherapy.³ Such modifications include minimizing fluid intake before bed (particularly caffeine and alcohol), restriction of total fluid consumption, emptying the bladder before bed, increasing exercise and fitness levels, earlier dosing of medications such as diuretics, and elevating the legs above heart level for a few hours before going to bed (for patients with peripheral edema).

Safety

Noctiva has a Boxed Warning regarding hyponatremia.¹ Use of Noctiva is contraindicated in patients at increased risk of severe hyponatremia such as patients with excessive fluid intake, illness that may cause fluid or electrolyte imbalances, and in patients using loop diuretics or systemic or inhaled glucocorticoids. It is recommended to check serum sodium concentrations prior to initiating or resuming Noctiva and throughout treatment. If hyponatremia occurs, Noctiva may need to be temporarily or permanently discontinued. Noctiva is contraindicated in patients with hyponatremia and among those with a history of hyponatremia. Also, patients with polydipsia or primary nocturnal enuresis should not use Noctiva. Do not administer Noctiva concomitantly with loop diuretics or with systemic or inhaled glucocorticoids. Patients with renal impairment with an estimated glomerular filtration rate < 50 mL/min/1.73 m² should not use Noctiva. Those with known or suspected syndrome of inappropriate antidiuretic hormone secretion should not use Noctiva. Do not utilize Noctiva during illnesses that may cause fluid or electrolyte imbalance, such as gastroenteritis, salt-wasting nephropathies, or systemic infection. Noctiva is contraindicated in patients with congestive heart failure (CHF) [New York Heart Association {NYHA} class II to IV] and among those with uncontrolled hypertension because the fluid retention in these conditions increases the risk of worsening the underlying condition. Also, Noctiva is not recommended in patients at risk for increased intracranial pressure or those with a of urinary retention, and should be used with caution (e.g., monitoring of volume status) in patients with NYHA class I CHF. Noctiva is contraindicated for the treatment of primary nocturnal enuresis because of reports of hyponatremia-related seizures in pediatric patients treated with other intranasal formulations of desmopressin. Trials involving Noctiva have not been performed in pediatric patients.

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Guidelines

A consensus statement on the diagnosis and treatment of nocturia was published by the International Continence Society in 2019.² There was consensus that fluid restriction should be advised for all desmopressin-treated patients. Newer desmopressin formulations, including Nocdurna® (desmopressin acetate sublingual tablets [27.7 mcg and 55.3 mcg]) and Noctiva, are generally regarded as low-dose desmopressin products. Low-dose formulations are appropriate in the absence of contraindications to desmopressin therapy.

Oral desmopressin tablets are cited as another formulation in the consensus statement (available as 100 mcg and 200 mcg tablets in the US).² This is noted to be an option for certain patients, although lower-dose formulations should be used when concomitant hyponatremia risk factors are present.

Of note, it is uncertain how the pharmacokinetic profile of Noctiva aligns with the other FDA-approved nasal desmopressin products because there are no comparative bioavailability studies and Noctiva contains a novel excipient, cyclopentadecanolide, which enhances absorption.¹ The consensus statement suggests that pharmacodynamic and pharmacokinetic studies in nocturia patients during an overnight evaluation would be ideal to characterize plasma desmopressin levels and rationale for dose differentiation.²

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Noctiva. All approvals are provided for the duration noted below. Due to the specialized skills required for evaluation and diagnosis of patients treated with Noctiva, as well as the monitoring required for adverse events and long-term efficacy, approval requires Noctiva to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Noctiva is recommended in those who meet the following criteria:

FDA-Approved Indication

1. **Nocturia due to Nocturnal Polyuria.** Approve for 1 year if the patient meets ALL of the following (A, B, C, D, E, F, G and H):
 1. Patient is ≥ 50 years of age; AND
 1. The diagnosis of nocturnal polyuria has been confirmed with a 24-hour urine collection before treatment initiation AND the patient meets ONE of the following (i or ii):
 1. Patient is < 65 years of age: The nocturnal urine volume exceeds 20% of the total 24-hour urine volume; OR
 1. Patient is ≥ 65 years of age: The nocturnal urine volume exceeds 33% of the total 24-hour urine volume; AND
 1. Prior to desmopressin therapy, patient awakens at least two times per night to void; AND
 1. Patient has serum sodium concentrations within the normal range (135 to 145 mmol/L); AND
 1. Prescriber has verified that the patient does not have the following conditions/circumstances in which use of Noctiva is not recommended (i, ii, iii, iv, v, or vi):
 1. Currently receiving loop diuretics; OR
Note: Examples of loop diuretics include furosemide, torsemide, bumetanide
 1. Currently receiving systemic or inhaled glucocorticoids; OR

1. Renal impairment with an estimated glomerular filtration rate < 50 mL/min/1.73 m²; OR
1. New York Heart Association class II to IV congestive heart failure; OR
1. Polydipsia; OR
1. Known or suspected syndrome of inappropriate antidiuretic hormone secretion; AND
1. Patient has tried non-pharmacologic techniques or lifestyle interventions to manage the nocturia; AND

Note: Examples of non-pharmacologic techniques for nocturia include nighttime fluid restriction, avoidance of caffeine and alcohol, earlier timing of medications, leg elevation, or use of compression stockings.
1. Patient tried one of Nocdurna (desmopressin acetate sublingual tablets) or oral desmopressin acetate tablets (DDAVP tablets, generic); AND
1. The medication is prescribed by or in consultation with a nephrologist, urologist, geriatrician, or endocrinologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Noctiva is not recommended in the following situations:

84. **Primary Nocturnal Enuresis.** Use of Noctiva is contraindicated for the treatment of patients with primary nocturnal enuresis.¹ Reports of hyponatremia-related seizures have occurred in pediatric patients treated with other intranasal formulations of desmopressin.
85. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

- Freestyle Libre CGM System – Abbott
- Freestyle Libre 2 CGM System – Abbott
- Freestyle Libre 3 CGM System – Abbott
- Guardian Connect CGM System – Medtronic
- Guardian 4 CGM System – Medtronic

REVIEW DATE: 01/17/2024; selected revision 02/07/2024 and 09/25/2024

OVERVIEW

The products targeted in this policy are continuous glucose monitoring (CGM) systems. Freestyle Libre and Freestyle Libre 2 are considered intermittently scanned CGM (isCGM) systems, whereas the other devices are considered real-time CGM (rtCGM) systems. Of note, throughout the policy, the term CGM “system” refers to all applicable components, including sensor, transmitter/reader, and receiver.

Of note, the Dexcom G5 CGM System was discontinued by the manufacturer as of June 2020. Per the manufacturer, sensor supply for this system, as well as technical support, would not be guaranteed after December 31, 2020.

Guidelines

The American Diabetes Association (ADA) Standards of Care (2024) comment on the role of rtCGM and isCGM in the management of diabetes.¹ The use of CGM devices should be considered from the outset of the diagnosis of diabetes that requires insulin management. The use of rtCGM (level of evidence A) or isCGM (level of evidence B) should be offered for diabetes management in adults with diabetes on multiple daily insulin injections or continuous subcutaneous insulin infusion (CSII). These devices also should be offered in youth with type 1 diabetes on multiple daily insulin injections or CSII (level of evidence A for rtCGM; level of evidence E for isCGM). In youth with type 2 diabetes, rtCGM or isCGM should be offered to those on multiple daily injections or CSII (level of evidence E). The use of rtCGM (level of evidence A) or isCGM (level of evidence B) should also be offered for diabetes management in adults with diabetes on basal insulin. In all cases, it is noted that the choice of device should be made based on the individual’s circumstances, preferences, and needs.

When used in addition to blood glucose monitoring in diabetes and pregnancy, CGM can help to achieve glycemic goals (level of evidence B).¹ CGM is recommended in pregnancies associated with type 1 diabetes (level of evidence A) and when used in addition to blood glucose monitoring, achieving traditional pre- and post-prandial goals, rtCGM can reduce the risk of large for gestational age infants and neonatal hypoglycemia in pregnant patients with type 1 diabetes (level of evidence A). There are insufficient data to support the use of CGM in all pregnant patients with type 2 diabetes or gestational diabetes. The decision to use CGM in such patients should be individualized based on treatment regimen, circumstances, preferences, and needs. In pregnant patients with pre-existing type 1 diabetes, insulin should be used (level

01/01/2022

© 2022. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

of evidence A); in pregnant patients with pre-existing type 2 diabetes, insulin is preferred for glycemic management (level of evidence B).

CGM is beneficial and recommended for individuals at high risk of hypoglycemia (level of evidence A).¹ Patients considered to be at high risk of hypoglycemia are a subset of patients at risk for hypoglycemia who either have a major hypoglycemia risk factor or have multiple other risk factors (determined by the health care professional). One of the major risk factors identified in the Standards of Care is a recent (within the past 3 to 6 months) level 2 or level 3 hypoglycemia event. Level 2 hypoglycemia is defined as a glucose value < 54 mg/dL. Level 3 hypoglycemia is defined as a severe event characterized by altered mental and/or physical status requiring assistance for treatment of hypoglycemia, irrespective of glucose level.

The American Association of Clinical Endocrinology (AACE) clinical practice guidelines regarding use of advanced technology in the management of persons with diabetes mellitus (2021) discuss CGM.² CGM is strongly recommended for all persons with diabetes treated with intensive insulin therapy, defined as three or more injections of insulin per day or the use of an insulin pump (Grade A; high strength of evidence). It is noted that CGM may be recommended for individuals with type 2 diabetes who are treated with less intensive insulin therapy; however, the strength of evidence is lower (Grade B; intermediate strength of evidence).

The AACE consensus statement for type 2 diabetes (2023) notes in patients with type 2 diabetes on basal insulin, clinical trials have shown that CGM is associated with increased time in range, improved hemoglobin A_{1c}, and decreased hypoglycemia, including severe hypoglycemic events.³

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of the targeted continuous glucose monitoring systems in this policy. All approvals are provided for the duration noted below.

Automation: If the patient has a claim for one insulin (any insulin) within the 130-day lookback period, the claim will adjudicate.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of the continuous glucose monitoring systems in this policy is recommended in those who meet the following criteria:

FDA-Approved Indication

19. Diabetes. Approve for 1 year if the patient meets ONE of the following (A or B):

A) Patient is using an insulin regimen; OR

Note: This includes patients on a basal insulin regimen, basal and prandial insulin regimen, prandial insulin regimen, or continuous subcutaneous insulin infusion (insulin pump).

B) Patient is taking a medication for glycemic control other than insulin AND meets ONE the following (i or ii):

i. Initial Therapy: Approve if the patient meets ONE of the following (a or b):

a) Patient had a level 2 hypoglycemia event in the past 6 months; OR

Note: A level 2 hypoglycemia event is defined as a blood glucose value < 54 mg/dL.

b) Patient had a level 3 hypoglycemia event in the past 6 months; OR

Note: A level 3 hypoglycemia event is defined as a severe event characterized by altered mental and/or physical status requiring assistance for treatment of hypoglycemia, irrespective of glucose level.

ii. Patient is Currently Receiving a Continuous Glucose Monitoring System: Approve if the patient meets ONE of the following (a or b):

a) Patient had a level 2 hypoglycemia event in the 6 months prior to initial continuous glucose monitoring system prescription; OR

Note: A level 2 hypoglycemia event is defined as a blood glucose value < 54 mg/dL.

b) Patient had a level 3 hypoglycemia event in the 6 months prior to initial continuous glucose monitoring system prescription.

Note: A level 3 hypoglycemia event is defined as a severe event characterized by altered mental and/or physical status requiring assistance for treatment of hypoglycemia, irrespective of glucose level.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of the continuous glucose monitoring systems in this policy is not recommended in the following situations:

52. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

REVIEW DATE: 04/10/2024; selected revision 06/05/2024 and 09/18/2024 (effective 01/01/2025)

OVERVIEW

The glucagon-like peptide-1 (GLP-1) receptor agonists and the GLP-1/glucose-dependent insulinotropic polypeptide-1 (GIP) agonist addressed in this policy are indicated as adjuncts to diet and exercise to improve glycemic control in adults with **type 2 diabetes**.^{1-7,13} Liraglutide, Trulicity, and Bydureon BCise are additionally indicated for type 2 diabetes in patients ≥ 10 years of age.^{2,6,7} Liraglutide, Ozempic, and Trulicity also have labeled indications related to cardiovascular (CV) risk reduction in adults with type 2 diabetes.^{4,6,7}

Guidelines

According to the American Diabetes Association Standards of Care (2024), pharmacologic therapy should be guided by person-centric treatment factors including comorbid conditions, as well as treatment goals, and preferences.⁸ Pharmacotherapy should be initiated at the time type 2 diabetes is diagnosed unless there are contraindications. Therapies, such as metformin or other agents, including combination therapy, that provide adequate efficacy to achieve and maintain treatment goals should be considered.

In adults with type 2 diabetes and established atherosclerotic cardiovascular disease (ASCVD), heart failure (HF), and/or chronic kidney disease (CKD), treatment should include agents that reduce CV or kidney disease risk.⁸ Among patients with type 2 diabetes with established ASCVD or indicators of high ASCVD risk, GLP-1 agonists with proven CV benefit (i.e., label indication of reducing CV disease events) or a sodium glucose co-transporter-2 (SGLT-2) inhibitor are preferred regardless of baseline metformin use. A GLP-1 agonist with proven CV benefit is an alternative to an SGLT-2 inhibitor if an SGLT-2 inhibitor is not tolerated or contraindicated in patients with CKD, regardless of baseline metformin use.

In patients without cardiorenal risk factors described above, the GLP-1 agonists are additionally recommended in patients based on glycemic needs.⁸ In general, higher efficacy approaches have a greater likelihood of achieving glycemic goals. The GLP-1 agonists, Ozempic and Trulicity (high dose) and the GLP-1/GIP agonist, Mounjaro (tirzepatide subcutaneous injection), are among the agents considered to have “very high” efficacy for glucose lowering; the other GLP-1 agonists are considered to have “high” efficacy for glucose lowering.

Weight management is also a treatment goal in individuals with type 2 diabetes due to multiple benefits including improved glycemic control, reduction in hepatic steatosis, and improvement in CV risk factors.⁸ The choice of therapy for glycemic control should support weight management goals; Mounjaro and Ozempic are noted to have the highest weight loss efficacy among the agents approved for glycemic

01/01/2023

© 2023. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

management. Additional weight management approaches, alone or in combination, should be used if needed to achieve an individual's weight loss goals (i.e., intensive behavioral therapy, weight loss pharmacotherapy, or metabolic surgery).

American Association of Clinical Endocrinologists statement on the comprehensive care for type 2 diabetes (2023) provides principles for the management of type 2 diabetes.¹¹ In patients with type 2 diabetes and established ASCVD or at high risk for ASCVD, GLP-1 agonists and SGLT-2 inhibitors are recommended. In a patient with type 2 diabetes and established ASCVD or are at high risk, a GLP-1 agonist with proven CV benefit (liraglutide, Ozempic, Trulicity) should be initiated as a first-line therapy independent of the glycemic goal or other antihyperglycemic treatments, including metformin; SGLT-2 inhibitors are an alternative. In patients with type 2 diabetes and ASCVD or at high risk of ASCVD use of a GLP-1 agonist is also recommended to reduce the risk of stroke. To reduce the risk of progression of diabetic kidney disease and CV disease in patients with type 2 diabetes, SGLT-2 inhibitors are recommended; GLP-1 agonists are also an option to reduce progression of albuminuria, renal function decline, and ASCVD risk in individuals with type 2 diabetes and diabetic kidney disease (Ozempic and Trulicity are cited). For patients with type 2 diabetes but without established or high risk for ASCVD, heart failure, stroke, or CKD, metformin should be the initial therapy unless contraindicated. In patients who are overweight or obese, the following therapies are recommended and listed in order of preference: Mounjaro, GLP-1 agonists, and SGLT-2 inhibitors. In patients with a history of hypoglycemia, at high risk of hypoglycemia, or at risk of severe complications from hypoglycemia, recommended therapies (in order of preference) are: GLP-1 agonists, SGLT-2 inhibitors, Mounjaro, thiazolidinediones, and dipeptidyl peptidase-4 inhibitors.

Kidney Diseases Improving Global Outcomes 2024 guidelines for the clinical evaluation and management of CKD recommend a long-acting GLP-1 agonist (prioritizing agents with documented CV benefits) in adults with type 2 diabetes and CKD who have not achieved individualized glycemic targets despite use of metformin and an SGLT-2 inhibitors, or who are unable to take those medications.¹²

A report of the American College of Cardiology and American Heart Association (2024) recommends GLP-1 agonists (liraglutide, Ozempic) and SGLT-2 inhibitors to reduce the risk of major adverse CV events in adults with type 2 diabetes and peripheral arterial disease.¹⁴

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of the GLP-1 agonists and the GLP-1/GIP agonist targeted in this policy. Of note, Saxenda® (liraglutide subcutaneous injection), Wegovy® (semaglutide subcutaneous injection), and Zepbound® (tirzepatide subcutaneous injection) are not indicated for the treatment of diabetes and are not targeted in this policy. All approvals are provided for the duration noted below.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage is recommended in those who meet the following criteria:

FDA-Approved Indication

1. **Type 2 Diabetes Mellitus.** Approve for 1 year if the patient meets ONE of the following (A or B):
1. If the request is for Adlyxin, Byetta, Mounjaro, Ozempic, Rybelsus: Approve if the patient is ≥ 18 years of age; OR
1. If the request is for Bydureon BCise, Trulicity, Victoza, liraglutide (authorized generic to Victoza): Approve if the patient is ≥ 10 years of age.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage is not recommended in the following situations:

53. **Weight Loss Treatment.** Saxenda (liraglutide subcutaneous injection) contains the same chemical entity as liraglutide (Victoza, authorized generic) and is indicated at a higher dose for chronic weight management. Wegovy (semaglutide subcutaneous injection) contains the same chemical entity as Ozempic and is indicated at a higher dose for chronic weight management. Zepbound (tirzepatide subcutaneous injection) contains the same chemical entity as Mounjaro and is indicated at the same doses for chronic weight management. Endocrine Society guidelines for pharmacological management of obesity (2015) advise against off-label prescribing of medications such as glucagon-like peptide-1 (GLP-1) receptor agonists for the sole purpose of producing weight loss.⁹ The American Gastroenterology Association guidelines for pharmacological interventions for adults with obesity only provide recommendations for the GLP-1 agonists approved for weight loss (i.e., Saxenda and Wegovy).¹¹ The GLP-1 agonists and GLP-1/glucose-dependent insulintropic polypeptide agonist in this policy are not FDA-approved for weight loss in a patient who is overweight (body mass index [BMI] ≥ 27 kg/m²) or obese (BMI ≥ 30 kg/m²) without type 2 diabetes. Note: If the patient has type 2 diabetes, refer to FDA-Approved Indication.
54. **Type 1 Diabetes Mellitus.** None of the glucagon-like peptide-1 (GLP-1) agonists or the GLP-1/glucose-dependent insulintropic polypeptide agonist are indicated in a patient with type 1 diabetes.¹⁻⁷ Addition of GLP-1 receptor agonists to insulin therapy resulted in small (0.2%) reductions in hemoglobin A_{1c} among patients with type 1 diabetes compared with insulin alone.⁸
55. **Prediabetes/Diabetes Prevention.** The glucagon-like peptide-1 (GLP-1) agonists and the GLP-1/glucose-dependent insulintropic polypeptide agonist are indicated in patients with type 2 diabetes; they are not indicated in a patient with elevated blood glucose who does not have type 2 diabetes. The American Diabetes Association Standards of Care (2024) state that metformin therapy should be considered in adults at high-risk of diabetes.⁸ Further, the standards note that metformin has the longest of safety data as a pharmacologic therapy for diabetes prevention. Note: If the patient has type 2 diabetes, refer to FDA-Approved Indication.
56. **Metabolic Syndrome.** The glucagon-like peptide-1 (GLP-1) agonists and the GLP-1/glucose-dependent insulintropic polypeptide agonist are not indicated in a patient with metabolic syndrome who does not have type 2 diabetes. Note: If the patient has type 2 diabetes, refer to FDA-Approved Indication.
57. **Concomitant Use with Glucagon-Like Peptide-1 (GLP-1) Agonists or GLP-1/ Glucose-Dependent Insulintropic Polypeptide (GIP) Agonist.** The GLP-1 agonists and the GLP-1/GIP agonist should

not be combined with each other or with any other GLP-1 agonists or GLP-1/GIP agonist. There are other GLP-1 and GLP-1/GIP products not included in this policy that are FDA-approved for weight loss and are not indicated for type 2 diabetes. Note: Examples of other GLP-1 agonists not included in this policy include but are not limited to Saxenda (liraglutide subcutaneous injection) and Wegovy (semaglutide subcutaneous injection). An example of a GLP-1/GIP agonist not included in this policy is Zepbound (tirzepatide subcutaneous injection).

- 58.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

REVIEW DATE: 06/05/2024; selected revision 09/18/2024 (effective 01/01/2025)

OVERVIEW

The glucagon-like peptide-1 (GLP-1) receptor agonists and the GLP-1/glucose-dependent insulinotropic polypeptide-1 (GIP) agonist addressed in this policy are indicated as adjuncts to diet and exercise to improve glycemic control in adults with **type 2 diabetes**.¹⁻⁸ Liraglutide, Trulicity, and Bydureon BCise are additionally indicated for type 2 diabetes in patients ≥ 10 years of age.^{3,7,8} Liraglutide, Ozempic, and Trulicity also have labeled indications related to cardiovascular (CV) risk reduction in adults with type 2 diabetes.^{5,7,8}

Guidelines

According to the American Diabetes Association Standards of Care (2024), pharmacologic therapy should be guided by person-centric treatment factors including comorbid conditions, as well as treatment goals, and preferences.⁹ Pharmacotherapy should be initiated at the time type 2 diabetes is diagnosed unless there are contraindications. Therapies, such as metformin or other agents, including combination therapy, that provide adequate efficacy to achieve and maintain treatment goals should be considered.

In adults with type 2 diabetes and established atherosclerotic cardiovascular disease (ASCVD), heart failure (HF), and/or chronic kidney disease (CKD), treatment should include agents that reduce CV or kidney disease risk.⁹ Among patients with type 2 diabetes with established ASCVD or indicators of high ASCVD risk, GLP-1 agonists with proven CV benefit (i.e., label indication of reducing CV disease events) or a sodium glucose co-transporter-2 (SGLT-2) inhibitor are preferred regardless of baseline metformin use. A GLP-1 agonist with proven CV benefit is an alternative to an SGLT-2 inhibitor if an SGLT-2 inhibitor is not tolerated or contraindicated in patients with CKD, regardless of baseline metformin use.

In patients without cardiorenal risk factors described above, the GLP-1 agonists are additionally recommended in patients based on glycemic needs.⁹ In general, higher efficacy approaches have a greater likelihood of achieving glycemic goals. The GLP-1 agonists, Ozempic and Trulicity (high dose) and the GLP-1/GIP agonist, Mounjaro (tirzepatide subcutaneous injection), are among the agents considered to have “very high” efficacy for glucose lowering; the other GLP-1 agonists are considered to have “high” efficacy for glucose lowering.

Weight management is also a treatment goal in individuals with type 2 diabetes due to multiple benefits including improved glycemic control, reduction in hepatic steatosis, and improvement in CV risk factors.⁹ The choice of therapy for glycemic control should support weight management goals; Mounjaro and Ozempic are noted to have the highest weight loss efficacy among the agents approved for glycemic

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

management. Additional weight management approaches, alone or in combination, should be used if needed to achieve an individual's weight loss goals (i.e., intensive behavioral therapy, weight loss pharmacotherapy, or metabolic surgery).

American Association of Clinical Endocrinologists statement on the comprehensive care for type 2 diabetes (2023) provides principles for the management of type 2 diabetes.¹² In patients with type 2 diabetes and established ASCVD or at high risk for ASCVD, GLP-1 agonists and SGLT-2 inhibitors are recommended. In a patient with type 2 diabetes and established ASCVD or are at high risk, a GLP-1 agonist with proven CV benefit (liraglutide, Ozempic, Trulicity) should be initiated as a first-line therapy independent of the glycemic goal or other antihyperglycemic treatments, including metformin; SGLT-2 inhibitors are an alternative. In patients with type 2 diabetes and ASCVD or at high risk of ASCVD, use of a GLP-1 agonist is also recommended to reduce the risk of stroke. To reduce the risk of progression of diabetic kidney disease and CV disease in patients with type 2 diabetes, SGLT-2 inhibitors are recommended; GLP-1 agonists are also an option to reduce progression of albuminuria, renal function decline, and ASCVD risk in individuals with type 2 diabetes and diabetic kidney disease (Ozempic and Trulicity are cited). For patients with type 2 diabetes but without established or high risk for ASCVD, heart failure, stroke, or CKD, metformin should be the initial therapy unless contraindicated. In patients who are overweight or obese, the following therapies are recommended and listed in order of preference: Mounjaro, GLP-1 agonists, and SGLT-2 inhibitors. In patients with a history of hypoglycemia, at high risk of hypoglycemia, or at risk of severe complications from hypoglycemia, recommended therapies (in order of preference) are: GLP-1 agonists, SGLT-2 inhibitors, Mounjaro, thiazolidinediones, and dipeptidyl peptidase-4 inhibitors.

Kidney Diseases Improving Global Outcomes 2024 guidelines for the clinical evaluation and management of CKD recommend a long-acting GLP-1 agonist (prioritizing agents with documented CV benefits) in adults with type 2 diabetes and CKD who have not achieved individualized glycemic targets despite use of metformin and an SGLT-2 inhibitors, or who are unable to take those medications.¹³

A report of the American College of Cardiology and American Heart Association (2024) recommends GLP-1 agonists (liraglutide, Ozempic) and SGLT-2 inhibitors to reduce the risk of major adverse CV events in adults with type 2 diabetes and peripheral arterial disease.¹⁴

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of the GLP-1 agonists and GLP-1/GIP agonist targeted in this policy. Of note, Saxenda® (liraglutide subcutaneous injection), Wegovy® (semaglutide subcutaneous injection), and Zepbound® (tirzepatide subcutaneous injection) are not indicated for the treatment of diabetes and are not targeted in this policy. All approvals are provided for the duration noted below.

Automation: The following automation is applied in this policy:

- **Adlyxin, Byetta, Mounjaro, Ozempic, Rybelsus:** If criteria for previous use of an oral medication for diabetes (not including Rybelsus or single-entity metformin) in the past 130 days are not met at the point of service, OR if the patient is < 18 years of age, coverage will be determined by Prior Authorization criteria.
- **Bydureon BCise, Trulicity, Victoza, liraglutide (authorized generic to Victoza):** If criteria for previous use of an oral medication for diabetes (not including Rybelsus or single-entity metformin) in the past 130 days are not met at the point of service, OR if the patient is < 10 years of age, coverage will be determined by Prior Authorization criteria.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage is recommended in those who meet the following criteria:

01/01/2023

© 2023. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

FDA-Approved Indication

2. **Type 2 Diabetes Mellitus.** Approve for 1 year if the patient meets ONE of the following (A or B):
2. If the request is for Adlyxin, Byetta, Mounjaro, Ozempic, Rybelsus: Approve if the patient is ≥ 18 years of age; OR
2. If the request is for Bydureon BCise, Trulicity, Victoza, liraglutide (authorized generic to Victoza): Approve if the patient is ≥ 10 years of age.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage is not recommended in the following situations:

59. **Weight Loss Treatment.** Saxenda (liraglutide subcutaneous injection) contains the same chemical entity as liraglutide (Victoza, authorized generic) and is indicated at a higher dose for chronic weight management. Wegovy (semaglutide subcutaneous injection) contains the same chemical entity as Ozempic and is indicated at a higher dose for chronic weight management. Zepbound (tirzepatide subcutaneous injection) contains the same chemical entity as Mounjaro and is indicated at the same doses for chronic weight management. Endocrine Society guidelines for pharmacological management of obesity (2015) advise against off-label prescribing of medications such as GLP-1 receptor agonists for the sole purpose of producing weight loss.¹⁰ The American Gastroenterology Association guidelines for pharmacological interventions for adults with obesity only provide recommendations for the GLP-1 agonists approved for weight loss (i.e., Saxenda and Wegovy).¹¹ The GLP-1 agonists and GLP-1/glucose-dependent insulintropic polypeptide-1 agonist in this policy are not FDA-approved for weight loss in a patient who is overweight (body mass index [BMI] ≥ 27 kg/m²) or obese (BMI ≥ 30 kg/m²) without type 2 diabetes. Note: If the patient has type 2 diabetes, refer to FDA-Approved Indication.
60. **Type 1 Diabetes Mellitus.** None of the GLP-1 agonists or GLP-1/ glucose-dependent insulintropic polypeptide-1 agonist are indicated for patients with type 1 diabetes.¹⁻⁸ Addition of GLP-1 receptor agonists to insulin therapy resulted in small (0.2%) reductions in hemoglobin A_{1c} among patients with type 1 diabetes compared with insulin alone.⁹
61. **Prediabetes/Diabetes Prevention.** GLP-1 agonists and the GLP-1/ glucose-dependent insulintropic polypeptide-1 agonist are not indicated in a patient with elevated blood glucose who does not have type 2 diabetes. The American Diabetes Association Standards of Care (2024) state that metformin therapy should be considered in adults at high-risk of diabetes.⁹ Further, the standards note that metformin has the longest of safety data as a pharmacologic therapy for diabetes prevention. Note: If the patient has type 2 diabetes, refer to FDA-Approved Indication.
62. **Metabolic Syndrome.** The GLP-1 agonists and the GLP-1/glucose-dependent insulintropic polypeptide-1 agonist are not indicated in a patient with metabolic syndrome who does not have type 2 diabetes. Note: If the patient has type 2 diabetes, refer to FDA-Approved Indication.
63. **Concomitant Use with Glucagon-Like Peptide-1 (GLP-1) Agonists or GLP-1/ Glucose-Dependent Insulintropic Polypeptide (GIP) Agonist.** The GLP-1 agonists and the GLP-1/GIP agonist should not be combined with each other or with any other GLP-1 agonists or GLP-1/GIP agonist. There are other GLP-1 and GLP-1/GIP products not included in this policy that are FDA-approved for weight loss and are not indicated for type 2 diabetes. Note: Examples of other GLP-1 agonists not included in this policy include but are not limited to Saxenda (liraglutide subcutaneous injection) and Wegovy

(semaglutide subcutaneous injection). An example of a GLP-1/GIP agonist not included in this policy is Zepbound (tirzepatide subcutaneous injection).

64. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Diabetes – Kerendia Prior Authorization Policy

- Kerendia® (finerenone tablets – Bayer)

REVIEW DATE: 08/07/2024

OVERVIEW

Kerendia, a nonsteroidal mineralocorticoid receptor antagonist (MRA), is indicated in adults with **chronic kidney disease (CKD) associated with type 2 diabetes** to reduce the risk of sustained estimated glomerular filtration rate (eGFR) decline, end-stage kidney disease, cardiovascular (CV) death, non-fatal myocardial infarction, and hospitalization for heart failure.¹

Per the prescribing information, do not initiate treatment with Kerendia if serum potassium is > 5.0 mEq/L.¹ Additionally, initiation of Kerendia is not recommended in patients with $\text{eGFR} < 25$ mL/min/1.73 m². Kerendia labeling includes a Warning regarding hyperkalemia and notes that the risk increases with decreasing kidney function. Monitoring of serum potassium and eGFR is recommended.

Clinical Efficacy

Efficacy of Kerendia was evaluated in two published Phase III, placebo-controlled trials, FIDELIO-DKD (n = 5,734) and FIGARO-DKD (n = 7,352).^{2,8} All patients were required to be treated with an angiotensin converting enzyme (ACE) inhibitor or angiotensin receptor blocker (ARB) at the maximum tolerated labeled dose for ≥ 4 weeks prior to the run-in visit. Additionally, patients were required to have a urinary albumin-to-creatinine ratio of ≥ 30 mg/g, in addition to other renal entry criteria.

Guidelines

The American Diabetes Association (ADA) Standards of Care (2024) recommend Kerendia for patients with type 2 diabetes and CKD with albuminuria treated with maximum tolerated doses of ACE inhibitors or ARBs, to improve CV outcomes and reduce the risk of CKD progression (level A recommendation).³ In individuals with type 2 diabetes and diabetic kidney disease, Kerendia is recommended to reduce the risk of hospitalization for heart failure (level A recommendation).

Additionally, in the section regarding CKD (Chapter 11), it is noted that in patients with diabetic kidney disease and type 2 diabetes, use of sodium glucose co-transporter-2 inhibitors (if eGFR is ≥ 20 mL/min/1.73 m²), a glucagon-like peptide-1 agonist, or Kerendia (if eGFR is ≥ 25 mL/min/1.73 m²), should be considered for CV risk reduction (level A recommendation). In patients with CKD and albuminuria, who are at increased risk for CV events or CKD progression, Kerendia is recommended to reduce CKD progression and CV events (level A recommendation).

The Kidney Disease: Improving Global Outcomes (KDIGO) Clinical Practice Guideline for Diabetes Management in CKD (2022) suggests use of Kerendia in patients with type 2 diabetes with $\text{eGFR} \geq 25$ mL/min/1.73 m², normal serum potassium, and albuminuria (≥ 30 mg/g) despite maximal tolerated doses of a renin-angiotensin-aldosterone system (RAAS) inhibitor.⁴ The rationale for adding an MRA to current standard of care, including ACE inhibitor or ARB, is that this combination has been proven to be an effective strategy to reduce albuminuria in patients with diabetes and CKD. The steroidal MRAs, spironolactone and eplerenone, have been shown to effectively reduce albuminuria; however, there are no data demonstrating that these agents reduce the risk of clinical outcomes. Kerendia reduces albuminuria and the risk of kidney and CV outcomes. The guidelines also note that Kerendia is most appropriate for

08/07/2024

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

patients with type 2 diabetes who are at high risk of CKD progression and CV events, because Kerendia can be added to an ACE/ARB and a sodium glucose co-transporter-2 inhibitor for treatment of type 2 diabetes and CKD.

A consensus report from the ADA/KDIGO (2022) for diabetes management in CKD states that Kerendia is recommended for patients with type 2 diabetes, $\text{eGFR} \geq 25 \text{ mL/min/1.73 m}^2$, normal serum potassium concentration, and albuminuria (albumin:creatinine ratio $\geq 30 \text{ g/g}$) despite a maximum tolerated dose of RAAS inhibitor therapy.¹⁰

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Kerendia. All approvals are provided for the duration noted below.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Kerendia is recommended in those who meet the following criteria:

FDA-Approved Indication

20. Diabetic Kidney Disease. Approve for 1 year if the patient meets ONE of the following (A or B):

- A) **Initial Therapy.** Approve if the patient meets ALL of the following (i, ii, iii, and iv):
 - i. Patient is ≥ 18 years of age; AND
 - ii. Patient has a diagnosis of type 2 diabetes; AND
 - iii. Patient meets ONE of the following (a or b):
 - a) Patient is currently receiving a maximally tolerated labeled dosage of an angiotensin converting enzyme (ACE) inhibitor or angiotensin receptor blocker (ARB); OR
 - b) According to the prescriber, patient has a contraindication to ACE inhibitor and ARB therapy; AND
 - iv. At baseline (prior to the initiation of Kerendia), patient meets ALL of the following (a, b, and c):
 - a) Estimated glomerular filtration rate $\geq 25 \text{ mL/min/1.73 m}^2$; AND
 - b) Urine albumin-to-creatinine ratio $\geq 30 \text{ mg/g}$; AND
 - c) Serum potassium level $\leq 5.0 \text{ mEq/L}$.
- B) **Patient is Currently Receiving Kerendia.** Approve if the patient meets ALL of the following (i, ii, and iii):
 - i. Patient is ≥ 18 years of age; AND
 - ii. Patient has a diagnosis of type 2 diabetes; AND
 - iii. Patient meets ONE of the following (a or b):
 - a) Patient is currently receiving a maximally tolerated labeled dosage of an angiotensin converting enzyme (ACE) inhibitor or angiotensin receptor blocker (ARB); OR
 - b) According to the prescriber, patient has a contraindication to ACE inhibitor and ARB therapy.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Kerendia is not recommended in the following situations:

65. Heart Failure (Treatment). Patients with a clinical diagnosis of heart failure with reduced ejection fraction (New York Heart Association [NYHA] Class II through IV) were excluded from FIDELIO-DKD and FIGARO-DKD.^{2,8} Kerendia was compared with eplerenone in the Phase IIb FINEARTS-HF trial (n = 1,066) among patients with heart failure with reduced ejection fraction and type 2 diabetes and/or chronic kidney disease.⁵ The primary endpoint was proportion of patients with > 30% decline in N-terminal pro-B-type natriuretic peptide (NT-proBNP) level at Day 90. Kerendia induced a > 30% decrease in NT-proBNP levels in a similar proportion of patients compared with eplerenone. Further data are needed to characterize the role of Kerendia in chronic heart failure management. Kerendia is not addressed in heart failure guidelines (outside of patients with diabetes and chronic kidney disease [CKD]). In an update to American College of Cardiology heart failure guidelines (2022), mineralocorticoid receptor antagonists (MRAs) [spironolactone, eplerenone] are recommended in patients with heart failure with reduced ejection fraction and NYHA Class II to IV symptoms, if estimated glomerular filtration rate is > 30 mL/min/1.73 m² and serum potassium is < 5 mEq/L.⁶ MRAs are also among the classes which may be considered for heart failure with mildly reduced ejection fraction and in selected patients with heart failure with preserved ejection fraction. An American College of Cardiology Expert Consensus Decision Pathway on Management of Heart Failure with Preserved Ejection Fraction (2023) lists Kerendia as a medication for patients with heart failure with preserved ejection fraction with concomitant diabetes and diabetic kidney disease.⁹ A 2023 update of the 2021 European Society of Cardiology guidelines for the treatment of acute and chronic heart failure recommend Kerendia in patients with type 2 diabetes and CKD to reduce the risk of heart failure hospitalization (Class I, Level A).¹¹

Note: For a patient with concomitant diabetic kidney disease and heart failure, refer to FDA-Approved Indication.

66. Hypertension (Treatment). Kerendia has not been evaluated for use in essential hypertension and is not mentioned in American College of Cardiology/American Heart Association hypertension guidelines (2017).⁷ Spironolactone and eplerenone are cited as secondary agents for management of hypertension and are noted to be common add-on therapies for resistant hypertension. Primary agents include thiazide diuretics, angiotensin converting enzyme inhibitors, angiotensin receptor blockers, and calcium channel blockers.

Note: For a patient with concomitant diabetic kidney disease and hypertension, refer to FDA-Approved Indication.

67. Concomitant Use with Spironolactone or Eplerenone. Spironolactone and eplerenone are steroidal mineralocorticoid receptor antagonists. Based on their mechanism of action, an increase in adverse events (e.g., hyperkalemia) would be expected if used concomitantly with Kerendia. Concomitant spironolactone or eplerenone use was not permitted in clinical trials.

68. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Diabetes – Symlin Prior Authorization Policy

- Symlin® (pramlintide subcutaneous injection – AstraZeneca)

REVIEW DATE: 08/07/2024

OVERVIEW

Symlin, an antihyperglycemic agent, is indicated as an adjunctive treatment in patients with **type 1 or type 2 diabetes** who use mealtime insulin therapy and who have failed to achieve desired glucose control despite optimal insulin therapy.¹

Guidelines/Consensus Statements

The American Diabetes Association Standards of Care (2024) do not provide a specific recommendation for use of Symlin in type 1 or type 2 diabetes and the American Association of Clinical Endocrinology (AACE) consensus statement of the comprehensive management of type 2 diabetes does not provide a recommendation for use of Symlin.^{2,4} The AACE and American College of Endocrinology guidelines for developing a comprehensive care plan (2022) recommend adding a glucagon-like peptide-1 agonist, a sodium glucose co-transporter-2 inhibitor, or Symlin (less commonly used) to reduce postprandial hyperglycemia, hemoglobin A_{1c}, and weight in individuals with type 2 diabetes who are treated with basal-bolus insulin therapy.³

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Symlin. All approvals are provided for the duration noted below.

Automation: If criteria for previous use of insulin (automated) within the past 130 days are not met at the point of service, coverage will be determined by Prior Authorization criteria.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Symlin is recommended in those who meet the following criteria:

FDA-Approved Indication

1. **Diabetes Mellitus, Type 1 or Type 2.** Approve for 1 year if the medication is prescribed in adjunct to insulin therapy.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Symlin is not recommended in the following situations:

1. **Weight Loss Treatment.** American Association of Clinical Endocrinologists/American College of Endocrinology obesity clinical practice guidelines (2016) comment that Symlin may lead to modest weight loss in diabetic patients but do not comment on a role for Symlin in management of obesity in non-diabetic patients.⁵ Guidelines from the American Gastroenterological Association (2022) do not address Symlin for weight loss.⁶ Other pharmacotherapies are available and indicated for weight loss.

PRIOR AUTHORIZATION POLICY

POLICY: Diabetes – Tzield Prior Authorization Policy

- Tzield® (teplizumab-mzwv intravenous infusion – Provention/Sanofi)

REVIEW DATE: 11/13/2024

OVERVIEW

Tzield, an anti-CD3 monoclonal antibody, is indicated to **delay the onset of Stage 3 type 1 diabetes** in adults and pediatric patients ≥ 8 years of age with Stage 2 type 1 diabetes.¹

Tzield is administered by intravenous infusion (over a minimum of 30 minutes) using body surface area-based dosing, once daily for 14 consecutive days.¹ Prior to initiating Tzield, obtain a complete blood count and liver enzyme tests. Use of Tzield is not recommended in patients with certain laboratory abnormalities, including lymphopenia, anemia, thrombocytopenia, neutropenia, or increased liver enzymes. Refer to the prescribing information for specific thresholds. Additionally, patients with laboratory or clinical evidence of acute infection with Epstein-Barr virus or cytomegalovirus should not receive Tzield, nor should patients with active serious infection or chronic active infection other than localized skin infections.

Clinical Efficacy

Efficacy of Tzield among patients at risk for development of type 1 diabetes was evaluated in one pivotal study called TN-10 (published) [n = 76].² Eligible patients were non-diabetic relatives of patients with type 1 diabetes and were ≥ 8 years of age at the time of randomization. Patients were also required to have two or more diabetes-related autoantibodies, confirmed on at least two occasions, within 6 months before randomization. In addition, patients were required to have had evidence of dysglycemia during an oral glucose tolerance test (OGTT). An abnormal OGTT was defined as meeting one of the following: fasting plasma glucose ≥ 110 to < 126 mg/dL; 2-hour postprandial plasma glucose ≥ 140 to < 200 mg/dL; or 30-, 60-, or 90-minute postprandial plasma glucose ≥ 200 mg/dL. Initially, two OGTTs were required within 52 days of enrollment; however, a protocol amendment was put in place requiring only one abnormal glucose tolerance test result for patients < 18 years of age.

Guidelines

American Diabetes Association (ADA) Standards of Care (2024) state that Tzield should be considered in selected individuals ≥ 8 years with stage 2 type 1 diabetes to delay the onset of symptomatic type 1 diabetes (Level B recommendation).³ Management should be in a specialized setting with appropriately trained personnel. According to the ADA Standards, screening for pre-symptomatic type 1 diabetes may be done by detection of autoantibodies to insulin, glutamic acid decarboxylase (GAD, GAD65), islet antigen 2 (IA-2 and IA-2b), or zinc transporter 8 (Level B recommendation).³ The presence of multiple islet autoantibodies is a risk factor for clinical diabetes. Testing for dysglycemia may be used to further forecast near-term risk. When multiple islet autoantibodies are identified, referral to a specialized center for further evaluation and/or consideration of a clinical trial or approved therapy to potentially delay the development clinical diabetes should be considered (Level B recommendation). A consensus guidance for monitoring individuals with islet autoantibody-positive pre-stage 3 type 1 diabetes (2024) state that when patients who are insulin autoantibody positive are initially identified, there is a need for confirmation using a second sample.⁴ Similar to the ADA Standards of Care, the guidance recommends that interested patients with stage 2 type 1 diabetes be offered trial participation or approved therapies.

Table 1. Autoantibodies Against Islet Autoantigens Detected in Stage 1 to 3 Type 1 Diabetes.⁴

11/13/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

IAA – Insulin autoantibody; GADA - Glutamic acid decarboxylase autoantibody; IA-2A – Insulinoma antigen-2 autoantibody; ICA512 – Islet cell autoantigen 512; ICA – Islet cell autoantibodies.

According to the ADA Standards, three distinct stages of type 1 diabetes can be identified.³ Clinical type 1 diabetes is referred to as “Stage 3 type 1 diabetes” and is characterized by overt hyperglycemia and the presence of symptoms. Diagnostic criteria include one of the following: fasting plasma glucose (FPG) $\geq$ 126 mg/dL; 2-hour postprandial glucose $\geq$ 200 mg/dL during an OGTT (75 grams); hemoglobin A_{1c} (HbA_{1c}) $\geq$ 6.5%; or random plasma glucose $\geq$ 200 mg/dL for a patient with classic symptoms of hyperglycemia or hyperglycemic crisis. “Stage 1 type 1 diabetes” and “Stage 2 type 1 diabetes” are pre-symptomatic states characterized by autoimmunity (i.e., multiple autoantibodies) but no overt diabetes symptoms. In Stage 1 disease, patients have a normal glycemic level. In Stage 2 disease, dysglycemia is present but below the threshold considered overt for Stage 3 type 1 diabetes. Dysglycemia in Stage 2 type 1 diabetes involves FPG 100 to 125 mg/dL; 2-hour postprandial glucose 140 to 199 mg/dL; HbA_{1c} 5.7% to 6.4%; or a $\geq$ 10% increase in HbA_{1c}.

Screening for Type 1 Diabetes Risk

Multiple studies indicate that measuring islet autoantibodies in relatives of those with type 1 diabetes or in children from the general population can effectively identify those who will develop type 1 diabetes.³ A study reported the risk of progression to type 1 diabetes from the time of seroconversion to autoantibody positivity in pediatric cohorts from three countries. Of the 585 children who developed more than two autoantibodies, nearly 70% developed type 1 diabetes within 10 years and 84% developed type 1 diabetes within 15 years. These findings are highly significant because while the one group of patients was recruited from children of parents with type 1 diabetes, the other two groups were recruited from the general population. The findings in all three groups were the same, suggesting that the same sequence of events led to clinical disease in both “sporadic” and familial cases of type 1 diabetes. The risk of type 1 diabetes increases as the number of relevant autoantibodies detected increases.

Family history of autoimmune diabetes and personal or family history of allergic diseases or other autoimmune diseases increases risk of autoimmune diabetes compared with the general population.³ Individuals who test autoantibody positive should be either provided with or referred for counseling about the risk of developing diabetes, diabetes symptoms, diabetic ketoacidosis prevention, and consideration of additional testing as applicable to help determine if they meet criteria for intervention aimed at delaying progression.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Tzield. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Tzield as well as the monitoring required for adverse events and long-term efficacy, approval requires Tzield to be prescribed by or in consultation with a physician who specializes in the condition being treated. For certain criteria, verification is required as noted by **[verification required by prescriber]**. All reviews (approvals and denials) will be forwarded to the Medical Director for evaluation.

Documentation: Documentation is required where noted in the criteria as **[documentation required]**. Documentation may include, but is not limited to chart notes, laboratory tests, claims records, and/or other information.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Tzield is recommended in those who meet the following criteria:

11/13/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

FDA-Approved Indication

21. Type 1 Diabetes (Clinical/Stage 3), Delay of Onset. Approve for a one-time per lifetime course (14-day course) if the patient meets ALL of the following (A, B, C, D, E, F, G, H, I, J, and K):

- A) Patient is ≥ 8 years of age; AND
- B) Patient does NOT have a clinical diagnosis of type 1 diabetes (i.e., Stage 3 type 1 diabetes); AND
Note: Clinical type 1 diabetes is also referred to as Stage 3 type 1 diabetes. “Stage 1 type 1 diabetes” and “Stage 2 type 1 diabetes” are considered preclinical states and would not fall into the category of clinical type 1 diabetes.
- C) Patient does NOT have type 2 diabetes; AND
- D) Patient has at least one biological relative with a diagnosis of type 1 diabetes; AND
Note: Examples of relatives include first-degree relatives (e.g., parent, sibling) or other relatives (e.g., grandparent, aunt, uncle, cousin).
- E) Patient has tested positive for at least TWO of the following type 1 diabetes-related autoantibodies on two separate occasions: anti-glutamic acid decarboxylase 65 (anti-GAD65); anti-islet antigen-2 (anti-IA-2); islet-cell autoantibody (ICA); micro insulin; anti-zinc transporter 8 (anti-ZnT8) **[documentation required]**.
Note: The patient needs to have tested positive on two separate occasions, with at least two positive autoantibodies per occasion; however, the patient does not have to be positive for the same two antibodies on both occasions. For example, a positive test for anti-GAD65 and anti-IA-2 on one occasion, and positive test for ICA and micro insulin on another occasion would satisfy the requirement.
- F) Patient meets ONE of the following (i, ii, or iii) **[documentation required]**:
 - i. Patient has a 2-hour postprandial glucose level ≥ 140 to < 200 mg/dL during an oral glucose tolerance test in the preceding 2 months; OR
 - ii. Patient has a fasting plasma glucose level ≥ 100 to < 126 mg/dL in the preceding 2 months; OR
 - iii. Patient has an $HbA_{1c} \geq 5.7\%$ to $< 6.5\%$ in the preceding 2 months; AND
- G) At baseline (prior to the initiation of Tzield), patient does NOT have evidence of hematologic compromise, as defined by meeting the following (i, ii, iii, and iv) **[documentation required]**:
 - i. Lymphocyte count $\geq 1,000$ lymphocytes/mL; AND
 - ii. Hemoglobin ≥ 10 g/dL; AND
 - iii. Platelet count $\geq 150,000$ platelets/mL; AND
 - iv. Absolute neutrophil count $\geq 1,500$ neutrophils/mL; AND
- H) At baseline (prior to the initiation of Tzield), patient does NOT have evidence of hepatic compromise, as defined by meeting the following (i, ii, and iii) **[documentation required]**:
 - i. Alanine aminotransferase (ALT) ≤ 2 times the upper limit of normal (ULN); AND
 - ii. Aspartate aminotransferase (AST) ≤ 2 times the ULN; AND
 - iii. Bilirubin ≤ 1.5 times the ULN; AND
- I) According to the prescriber, the patient does NOT have any of the following (i, ii, or iii):
 - i. Laboratory or clinical evidence of acute infection with Epstein-Barr Virus or cytomegalovirus; OR
 - ii. Active serious infection; OR
 - iii. Chronic active infection (other than localized skin infection); AND
- J) Patient has NOT received Tzield in the past **[verification required by prescriber]**; AND
Note: Verify through claims that the patient has not previously received Tzield AND, if no claim for Tzield is present, the prescriber must attest that the patient has not previously received Tzield.
- K) The medication will be prescribed by an endocrinologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Tziel is not recommended in the following situations:

- 69. Type 1 Diabetes (Clinical/Stage 3), Treatment.** Note: Clinical type 1 diabetes is also referred to as Stage 3 type 1 diabetes. “Stage 1 type 1 diabetes” and “Stage 2 type 1 diabetes” are considered preclinical states and would not fall into the category of clinical type 1 diabetes. Tziel is not indicated for patients with a diagnosis of clinical type 1 diabetes (i.e., Stage 3 type 1 diabetes).
- 70.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Dichlorphenamide Prior Authorization Policy

- Keveyis® (dichlorphenamide tablets – Xeris, generic)

REVIEW DATE: 01/08/2025

OVERVIEW

Dichlorphenamide, a carbonic anhydrase inhibitor, is indicated for the treatment of **primary hyperkalemic periodic paralysis** (HyperPP), **primary hypokalemic periodic paralysis** (HypoPP), and related variants.¹ These conditions are heterogeneous and response to dichlorphenamide may vary; therefore, prescribers should evaluate the patient's response to dichlorphenamide after 2 months to decide whether it should be continued.

Disease Overview

The primary periodic paralyses are rare muscle disorders caused by autosomal dominant genetic mutations in ion channels.^{2,3} The altered channels cannot properly regulate the flow of ions into muscle cells, which reduces the ability of skeletal muscles to contract, leading to severe muscle weakness or paralysis.⁴ Genetic testing is recommended as the first diagnostic step; a heterozygous pathogenic mutation can be identified in 60% to 70% of periodic paralysis cases.⁵ When a genetic mutation cannot be identified, periodic paralyses can be distinguished based on clinical presentation. Other causes of hypokalemia or hyperkalemia should be excluded.⁵

Regarding treatment, oral potassium salts can be taken as maintenance/prophylactic therapy for patients with HypoPP; however, this does not completely prevent attacks.⁶ Although data are limited to case reports and single-blind trials, acetazolamide, another carbonic anhydrase inhibitor, has been used historically for primary periodic paralysis. Acetazolamide treatment is beneficial in approximately 50% of patients with HypoPP and it has no effect in 30% of affected patients. It can also exacerbate symptoms in 20% of patients. Dichlorphenamide has been reported to be 30 times more potent than acetazolamide in vitro.⁷ Prior to initiating dichlorphenamide it is important to verify if the patient has had exacerbation with acetazolamide, since dichlorphenamide is considered to be more potent and may potentially lead to more exacerbations.⁸

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of dichlorphenamide. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with dichlorphenamide, as well as the monitoring required for adverse events and long-term efficacy, initial approval requires dichlorphenamide to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of dichlorphenamide is recommended in those who meet one of the following criteria:

FDA-Approved Indications

01/08/2025

© 2025. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

32. Hypokalemic Periodic Paralysis (HypoPP) and Related Variants. Approve for the duration noted if the patient meets ONE of the following (A or B):

1. Initial Therapy. Approve for 2 months if the patient meets ALL of the following (i, ii, iii, iv, v, and vi):
 1. Patient has a confirmed diagnosis of primary hypokalemic periodic paralysis by meeting at least ONE of the following (a, b, or c):
 1. Patient has had a serum potassium concentration of less than 3.5 mEq/L during a paralytic attack; OR
 1. Patient has a family history of the condition; OR
 1. Patient has a genetically confirmed skeletal muscle calcium or sodium channel mutation; AND
 1. The prescriber has excluded other reasons for acquired hypokalemia; AND
Note: Examples of other reasons for acquired hypokalemia include renal, adrenal, or thyroid dysfunction; renal tubular acidosis; and diuretic or laxative abuse.
 1. Patient has had improvements in paralysis attack symptoms with potassium intake; AND
 1. Patient has tried oral acetazolamide therapy; AND
 1. According to the prescriber, acetazolamide therapy did not worsen the paralytic attack frequency or severity in the patient; AND
 1. The medication is prescribed by or in consultation with a neurologist or a physician who specializes in the care of patients with primary periodic paralysis (e.g., muscle disease specialist, physiatrist); OR
2. Patient is Currently Receiving Dichlorphenamide. Approve for 1 year if the patient has responded to dichlorphenamide (e.g., decrease in the frequency or severity of paralytic attacks) as determined by the prescriber.

33. Hyperkalemic Periodic Paralysis (HyperPP) and Related Variants. Approve for the duration noted if the patient meets ONE of the following (A or B):

1. Initial Therapy. Approve for 2 months if the patient meets ALL of the following (i, ii, iii, iv and v):
1. Patient has a confirmed diagnosis of primary hyperkalemic periodic paralysis by meeting at least ONE of the following criteria (a, b, c, or d):
 1. Patient has had an increase from baseline in serum potassium concentration of greater than or equal to 1.5 mEq/L during a paralytic attack; OR
 1. Patient has had a serum potassium concentration during a paralytic attack of greater than 5.0 mEq/L; OR
 1. Patient has a family of the condition; OR
 1. Patient has a genetically confirmed skeletal muscle sodium channel mutation; AND
1. The prescriber has excluded other reasons for acquired hyperkalemia; AND
Note: Examples of other reasons for acquired hyperkalemia include drug abuse, renal dysfunction, and adrenal dysfunction.
1. Patient has tried oral acetazolamide therapy; AND
1. According to the prescriber, acetazolamide therapy did not worsen the paralytic attack frequency or severity in the patient; AND
1. The medication is prescribed by or in consultation with a neurologist or a physician who specializes in the care of patients with primary periodic paralysis (e.g., muscle disease specialist, physiatrist); OR
2. Patient is Currently Receiving Dichlorphenamide. Approve for 1 year if the patient has responded to dichlorphenamide (e.g., decrease in the frequency or severity of paralytic attacks) as determined by the prescriber.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of dichlorphenamide is not recommended in the following situations:

3. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Dronabinol Products Prior Authorization with Step Therapy Policy

- Marinol® (dronabinol capsules – ThePharmaNetwork, generic)
- Syndros® (dronabinol oral solution – Insys/Benuvia)

REVIEW DATE: 12/11/2024

OVERVIEW

Dronabinol capsules and Syndros are cannabinoids indicated for the following uses:^{1,2}

- **Anorexia associated with weight loss**, in patients with Acquired Immune Deficiency Syndrome (AIDS).
- **Nausea and vomiting associated with cancer chemotherapy**, in patients who have failed to respond adequately to conventional antiemetic treatments.

Guidelines

The National Comprehensive Cancer Network (NCCN) guidelines regarding the treatment of emesis (version 2.2024 – September 27, 2024) include various antiemetic regimens depending upon the emetogenic potential of the chemotherapy agent(s) being administered.³ For breakthrough emesis, the guidelines recommend adding an agent from a different drug class to the current regimen, but no preference is given among specific products. Dronabinol is included in the list of medications for the treatment of refractory nausea or emesis. Other recommended agents for breakthrough nausea or emesis include serotonin receptor antagonists, olanzapine, lorazepam, haloperidol, metoclopramide, scopolamine, prochlorperazine, promethazine, and dexamethasone. The guidelines also note that dronabinol capsules are not bioequivalent to the oral solution.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of dronabinol products. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

I. Coverage of dronabinol capsules is recommended in those who meet one of the following criteria:

FDA-Approved Indications

24. Anorexia Associated with Weight Loss in a Patient with Acquired Immune Deficiency Syndrome (AIDS). Approve for 6 months if the patient meets ONE of the following (A or B):

A) Generic dronabinol capsules are requested; OR

B) If brand Marinol is prescribed, the patient meets BOTH of the following (i and ii):

- i. Patient has tried generic dronabinol capsules; AND
- ii. The Brand product is being requested due to a formulation difference in the inactive ingredient(s) [e.g., difference in dyes, fillers, preservatives] between the Brand and the

12/11/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

bioequivalent generic product which, per the prescriber, would result in a significant allergy or serious adverse reaction.

2. **Nausea and Vomiting Associated with Cancer Chemotherapy.** Approve for 1 year if the patient meets BOTH of the following (A and B):
 - A) Patient has failed to respond adequately to at least TWO conventional antiemetic treatments; AND
Note: Examples of conventional antiemetic treatments include selective serotonin [5-HT₃] receptor antagonists (such as ondansetron, granisetron, Anzemet [dolasetron], Aloxi [palonosetron injection]), Akynzeo (netupitant/palonosetron capsules), Emend (aprepitant capsules), Varubi (rolapitant tablets), metoclopramide, prochlorperazine, dexamethasone, olanzapine.
 - B) Patient meets ONE of the following (i or ii):
 - i. Generic dronabinol capsules are requested; OR
 - ii. If brand Marinol is prescribed, the patient meets BOTH of the following (a and b):
 - a) Patient has tried generic dronabinol capsules; AND
 - b) The Brand product is being requested due to a formulation difference in the inactive ingredient(s) [e.g., difference in dyes, fillers, preservatives] between the Brand and the bioequivalent generic product which, per the prescriber, would result in a significant allergy or serious adverse reaction.

II. Coverage of Syndros is recommended in those who meet one of the following criteria:

FDA-Approved Indications

1. **Anorexia Associated with Weight Loss in a Patient with Acquired Immune Deficiency Syndrome (AIDS).** Approve for 6 months if the patient meets ONE of the following (A or B):
 - A) Patient has tried generic dronabinol capsules; OR
 - B) Patient cannot swallow or has difficulty swallowing capsules.
2. **Nausea and Vomiting Associated with Cancer Chemotherapy.** Approve for 1 year if the patient meets BOTH of the following (A and B):
 - A) Patient has failed to respond adequately to at least TWO conventional antiemetic treatments; AND
Note: Examples of conventional antiemetic treatments include selective serotonin [5-HT₃] receptor antagonists (such as ondansetron, granisetron, Anzemet [dolasetron], Aloxi [palonosetron injection]), Akynzeo (netupitant/palonosetron capsules), Emend (aprepitant capsules), Varubi (rolapitant tablets), metoclopramide, prochlorperazine, dexamethasone, olanzapine.
 - B) Patient meets ONE of the following (i or ii):
 - i. Patient has tried generic dronabinol capsules; OR
 - ii. Patient cannot swallow or has difficulty swallowing capsules.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of dronabinol products is not recommended in the following situations:

4. **Chronic Non-Cancer Pain.** Based on a review of published studies, there is insufficient evidence for the use of dronabinol in non-cancer pain due to the small study sizes and moderate to high risk of bias to allow for a definitive conclusion.⁴ In the two studies reviewed, the authors reported mixed effects for pain measures for dronabinol. More data are needed to define the place in therapy of dronabinol in the treatment of chronic non-cancer pain.

5. **Multiple Sclerosis.** Results from one published, randomized, double-blind, placebo-controlled study (n = 498) demonstrated that dronabinol has no overall effect on the progression of multiple sclerosis in patients with primary and secondary progressive multiple sclerosis.⁵ More data are needed to define the place in therapy of dronabinol in the treatment of multiple sclerosis.
6. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Droxidopa Prior Authorization Policy

- Northera® (droxidopa capsules – Lundbeck, generic)

REVIEW DATE: 12/11/2024

OVERVIEW

Droxidopa, a norepinephrine-type product, is indicated for the treatment of orthostatic dizziness, lightheadedness, or the “feeling that one is about to black out” in adults with symptomatic **neurogenic orthostatic hypotension (NOH)** caused by primary autonomic failure (Parkinson’s disease, multiple system atrophy, and pure autonomic failure), dopamine beta-hydroxylase deficiency, and non-diabetic autonomic neuropathy.¹

Disease Overview

Orthostatic hypotension (OH) is a sustained reduction in systolic blood pressure (SBP) of at least 20 mmHg or diastolic blood pressure (DBP) of 10 mmHg within 3 minutes of standing or head-up tilt to at least 60° on a tilt table.² OH may be symptomatic or asymptomatic, with only symptomatic OH requiring treatment. NOH is a specific subset of this condition, in which OH is due to inadequate release of norepinephrine from sympathetic vasomotor neurons leading to vasoconstrictor failure. NOH is a rare, chronic and often debilitating condition that is associated with Parkinson’s disease, multiple system atrophy, and pure autonomic failure, and with peripheral neuropathies and ganglionopathies that affect the autonomic nerves.²⁻⁴ Symptoms of NOH include dizziness, lightheadedness, blurred vision, fatigue, and fainting upon standing up. These symptoms can adversely affect patients’ quality of life and ability to conduct activities of daily living that involve standing or walking. Treatment of symptomatic NOH is aimed at increasing standing systolic blood pressure into the range of compensatory cerebrovascular autoregulation (approximately 50 to 150 mmHg).⁵ Unapproved pharmacologic agents include fludrocortisone, dihydroergotamine (oral), indomethacin (oral or intravenous), pyridostigmine, and atomoxetine.^{2-4,6} Midodrine, an alpha₁-agonist, is the only other medication approved with a similar indication (treatment of symptomatic orthostatic hypotension) to droxidopa.⁷

Guidelines

Consensus panel recommendations initiated by the American Autonomic Society and the National Parkinson Foundation for the screening, diagnosis, and treatment of NOH and associated supine hypertension were published in 2017.⁸ Once a patient is diagnosed with NOH, the goals of treatment should be to reduce the burden of symptoms (especially falls), prolong standing time, and restore independence in activities of daily living. The recommendations propose a four-step treatment algorithm for NOH: assessing and adjusting preexisting medications that may be causing or exacerbating NOH, utilizing non-pharmacologic approaches (e.g., blood volume repletion, increased salt intake, physical conditioning, compression garments, elevating the head of the bed), implementing single-agent pharmacologic treatment, and with great caution, combining pharmacologic treatments. Recommended treatments include midodrine, droxidopa, fludrocortisone, and pyridostigmine. The initial choice of NOH treatments should be individualized and should consider severity, comorbid disease (especially cardiac or renal failure), and treatment goals. Based on the experience of the consensus panel, the recommendation is to titrate to maximum tolerable dose of a single medication and then, if symptomatic benefit is not obtained, consider switching to a different medication or adding a second agent and titrate from its lowest starting dose.

POLICY STATEMENT

12/11/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Prior Authorization is recommended for prescription benefit coverage of droxidopa. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with droxidopa as well as the monitoring required for adverse events and long-term efficacy, approval requires droxidopa to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of droxidopa is recommended in those who meet the following criteria:

FDA-Approved Indication

9. Neurogenic Orthostatic Hypotension. Approve for 1 year if the patient meets ALL of the following (A, B, C, D, and E):

A) Patient is ≥ 18 years of age; AND

B) Patient has been diagnosed with symptomatic neurogenic orthostatic hypotension due to primary autonomic failure (Parkinson's disease, multiple system atrophy, and pure autonomic failure), dopamine beta-hydroxylase deficiency, or non-diabetic autonomic neuropathy; AND

C) Patient has tried two other medications for the treatment of neurogenic orthostatic hypotension; AND

Note: Examples of other medications for the treatment of neurogenic orthostatic hypotension include atomoxetine, dihydroergotamine, fludrocortisone, indomethacin, midodrine, and pyridostigmine.

D) Patient has initiated non-pharmacological measures including but not limited to elevation of the head of the bed, orthostatic compression garments, and appropriate physical training; AND

E) The medication has been prescribed by or in consultation with a cardiologist or a neurologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of droxidopa is not recommended in the following situations:

7. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Enspryng Prior Authorization Policy

- Enspryng® (satralizumab-mwge subcutaneous injection – Genentech)

REVIEW DATE: 04/10/2024

OVERVIEW

Enspryng, an interleukin-6 receptor antagonist, is indicated for the treatment of **neuromyelitis optica spectrum disorder** (NMOSD) in adults who are anti-aquaporin-4 antibody positive.¹

Disease Overview

NMOSD is a rare, relapsing, autoimmune disorder of the brain and spinal cord with optic neuritis and/or myelitis as predominant characteristic symptoms.² NMOSD often causes significant, permanent damage to vision and/or spinal cord function resulting in blindness or impaired mobility.³ Patients may experience pain, paralysis, loss of bowel and bladder control, loss of visual acuity, and uncontrolled motor functions. Complications can lead to death.

Recommendations

The Neuromyelitis Optica Study Group (NEMOS) published revised recommendations for the treatment of NMOSD in 2024.⁴ The standard of care for the treatment of NMOSD attacks (for both AQP4-IgG-positive and double-negative cases) are high-dose glucocorticoids and/or apheresis therapy. Long-term immunotherapy is recommended for patients with AQP4-IgG-positive NMOSD. NEMOS notes the first-choice therapies for the treatment of AQP4-IgG-positive NMOSD are Enspryng, Soliris® (eculizumab intravenous infusion), Ultomiris® (ravulizumab-cwyz intravenous infusion), Uplizna® (inebilizumab-cdon intravenous infusion), and rituximab. The order of preference for these therapies is unclear and further comparative trials and real-world data are needed. The choice of treatment is dependent on several factors, including disease activity and severity, mode and onset of action, possibility to combine it with immunosuppressive drugs, effect on autoimmune and other comorbidities, gender (family planning issues), frequency and route of administration, side effect profile as well as patient and physician preference. In general, if a patient fails a first-choice treatment, another first-choice treatment should be tried; other options include use of a second-choice treatment (azathioprine, mycophenolate mofetil, low-dose oral glucocorticoids) or the addition of a second-choice treatment to the regimen.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Enspryng. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Enspryng as well as the monitoring required for adverse events and long-term efficacy, approval requires Enspryng to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Enspryng is recommended in those who meet the following criteria:

FDA-Approved Indication

- 34. Neuromyelitis Optica Spectrum Disorder.** Approve for the duration noted if the patient meets ONE of the following (A or B):
- E) Initial Therapy.** Approve for 1 year if the patient meets ALL of the following (i, ii, and iii):
- vii.** Patient is ≥ 18 years of age; AND
 - viii.** Diagnosis was confirmed by a positive blood serum test for anti-aquaporin-4 antibody; AND
 - ix.** The medication is being prescribed by or in consultation with a neurologist.
- F) Patient is Currently Receiving Enspryng.** Approve for 1 year if the patient meets ALL of the following (i, ii, iii, and iv):
- ix.** Patient is ≥ 18 years of age; AND
 - x.** Diagnosis was confirmed by a positive blood serum test for anti-aquaporin-4 antibody; AND
 - xi.** According to the prescriber, patient has had clinical benefit from the use of Enspryng; AND
Note: Examples of clinical benefit include reduction in relapse rate, reduction in symptoms (e.g., pain, fatigue, motor function), and a slowing in progression of symptoms.
 - xii.** The medication is being prescribed by or in consultation with a neurologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Enspryng is not recommended in the following situations:

- 71. Concomitant Use with a Rituximab Product, Soliris (eculizumab intravenous infusion), Ultomiris (ravulizumab-cwyz intravenous infusion), or Uplizna (inebilizumab-cdon intravenous infusion).** There is no evidence to support concomitant use of Enspryng with a rituximab product, Soliris, Ultomiris, or Uplizna.
- 72.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Enzyme Replacement Therapy – Aldurazyme Prior Authorization Policy

- Aldurazyme® (laronidase intravenous infusion – Genzyme)

REVIEW DATE: 04/24/2024

OVERVIEW

Aldurazyme, a human α -L-iduronidase, is indicated for **Hurler and Hurler-Scheie forms of Mucopolysaccharidosis type I (MPS I)** and in patients with the **Scheie form who have moderate to severe symptoms**.¹

Disease Overview

MPS I is a rare autosomal recessive, lysosomal storage disease characterized by the deficiency of α -L-iduronidase.² Patients with MPS I are unable to degrade dermatan and heparin sulfate, resulting in the accumulation of glycosaminoglycans within lysosomes. Over time, the accumulation of glycosaminoglycans leads to progressive tissue damage,³ ultimately resulting in multiorgan dysfunction.^{2,3} Patients with MPS I commonly have a characteristic face, corneal clouding, cardiomyopathy, enlarged tongue, respiratory insufficiency, hepatosplenomegaly, hernias, dysostosis multiplex, joint stiffness, and cognitive impairment.^{4,5} MPS I is commonly classified as three separate entities, Hurler syndrome (severe form), Hurler-Scheie syndrome (intermediate form) and Scheie syndrome (mild form).²⁻⁴ However, this classification system is based on disease severity and age of onset, not on any biochemical differences between the three syndromes.⁵ All three forms of the disease are the result of the same enzymatic deficiency and represent varying degrees of severity along the disease continuum. The definitive diagnosis of MPS I is based on demonstrating deficient α -L-iduronidase activity in fibroblasts, leukocytes, plasma, or serum.^{2,3,5}

Specific treatments for MPS I include hematopoietic stem cell transplantation (HSCT) and enzyme replacement therapy.^{2,4,5} HSCT is indicated for the severe forms of MPS I, in children < 2 years of age who are cognitively intact.^{2,4} HSCT has been shown to preserve intellectual development, reverse some aspects of somatic disease and increase survival.^{2,4,5} Enzyme replacement therapy (Aldurazyme) does not cross the blood-brain barrier and is unlikely to improve cognitive or neurologic function.² Therefore, Aldurazyme is appropriate in children < 2 years of age who have already experienced cognitive decline, or who are cognitively intact with severe physical disease prior to HSCT to improve their health. Aldurazyme is also recommended in older patients with or without cognitive or neurologic decline.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Aldurazyme. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Aldurazyme as well as the monitoring required for adverse events and long-term efficacy, approval requires Aldurazyme to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Aldurazyme is recommended in those who meet the following criteria:

FDA-Approved Indication

22. Mucopolysaccharidosis Type I (Hurler Syndrome, Hurler-Scheie Syndrome, and Scheie Syndrome). Approve for 1 year if the patient meets BOTH of the following (A and B):

- A)** The diagnosis is established by ONE of the following (i or ii):
 - i.** Patient has a laboratory test demonstrating deficient α -L-iduronidase activity in leukocytes, fibroblasts, plasma, or serum; OR
 - ii.** Patient has a molecular genetic test demonstrating biallelic pathogenic or likely pathogenic α -L-iduronidase (*IDUA*) gene variants; AND
- B)** Aldurazyme is prescribed by or in consultation with a geneticist, endocrinologist, a metabolic disorder sub-specialist, or a physician who specializes in the treatment of lysosomal storage disorders.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Aldurazyme is not recommended in the following situations:

- 73.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Enzyme Replacement Therapy – Elaprase Prior Authorization Policy

- Elaprase® (idursulfase intravenous infusion – Shire Human Genetic Therapies)

REVIEW DATE: 04/24/2024

OVERVIEW

Elaprase, human iduronate-2-sulfatase (idursulfase), is indicated for **Hunter syndrome (Mucopolysaccharidosis type II [MPS II])**.¹

Disease Overview

MPS II or Hunter syndrome, is a rare, X-linked lysosomal storage disorder characterized by a deficiency of iduronate-2-sulfatase leading to the accumulation of glycosaminoglycans dermatan sulfate and heparin sulfate.^{2,3} Males are almost exclusively affected, although there have been a few case reports of females with Hunter syndrome.^{3,4} The onset, progression, and severity of MPS II is variable.²⁻⁴ Most of the patients with MPS II have a severe form with neurologic involvement leading to cognitive impairment and neurologic regression.^{3,4} Other manifestations of Hunter syndrome include coarse facial features, hepatosplenomegaly, cardiac and respiratory disease, short stature, and stiff joints and contractures.^{2,3} The definitive diagnosis of MPS II is established by demonstrating deficient iduronate-2-sulfatase activity in leukocytes, fibroblasts, serum, or plasma; or mutations in the iduronate-2-sulfatase gene.^{2,5} Definitive treatment of MPS II consists of enzyme replacement therapy with Elaprase.^{2-4,6} Hematopoietic stem cell transplantation has not demonstrated clear neurological benefit to date and is not recommended for MPS II due to the high rate of morbidity and mortality associated with this therapy.^{2,4}

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Elaprase. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Elaprase as well as the monitoring required for adverse events and long-term efficacy, approval requires Elaprase to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Elaprase is recommended in those who meet the following criteria:

FDA-Approved Indication

23. Mucopolysaccharidosis Type II (Hunter Syndrome). Approve for 1 year if the patient meets BOTH of the following (A and B):

A) The diagnosis is established by ONE of the following (i or ii):

- i.** Patient has a laboratory test demonstrating deficient iduronate-2-sulfatase activity in leukocytes, fibroblasts, serum, or plasma; OR
- ii.** Patient has a molecular genetic test demonstrating an iduronate-2-sulfatase gene variant; AND

04/24/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- B)** Elaprase is prescribed by or in consultation with a geneticist, endocrinologist, a metabolic disorder sub-specialist, or a physician who specializes in the treatment of lysosomal storage disorders.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Elaprase is not recommended in the following situations:

- 74.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Enzyme Replacement Therapy – Elfabrio Prior Authorization Policy

- Elfabrio® (pegunigalsidase alfa intravenous infusion – Chiesi)

REVIEW DATE: 07/03/2024

OVERVIEW

Elfabrio, a PEGylated, crosslinked, chemically modified human alpha-galactosidase A (α -Gal A) enzyme, is indicated for the treatment of **Fabry disease** in adults.¹ The amino acid sequence of one subunit of Elfabrio consists of 405 amino acids, of which 398 amino acids are identical to human alpha-galactosidase A. Elfabrio catalyzes the breakdown of globotriaosylceramide (GL-3) and other α -galactyl-terminated neutral glycosphingolipids to ceramide and galactose and reduces the deposition of GL-3 in the capillary endothelium of the kidney and certain other cell types.

Disease Overview

Fabry disease is a rare inherited X-linked lysosomal storage disorder due to absent or significantly reduced α -Gal activity leading to the accumulation of GL-3 in a wide variety of cells throughout the body.²⁻⁴ The accumulation of GL-3 leads to progressive multisystem disease, primarily impacting the kidney, heart, and nervous system.^{3,4} Fabry disease can be divided into two phenotypes. A severe, classical phenotype that more commonly occurs in men without α -Gal activity, whereas a generally milder non-classical (late-onset) phenotype is found in men and women with some residual α -Gal activity.^{2,3} Fabry disease is estimated to affect approximately 1 in 40,000 males and approximately 1 in 20,000 females. However, data from newborn screening programs suggest that the incidence of Fabry disease is generally underestimated and may equate to 1 per 3,100 live births, with late-onset phenotypes being more prevalent.⁵ The diagnosis of Fabry disease can be confirmed in males by demonstrating a deficiency in α -Gal activity, and in all patients by identifying a Fabry disease causing gene mutation.⁴ Long-term consequences of Fabry disease include hypertrophic cardiomyopathy, arrhythmias, renal failure, and stroke.³ The kidney disease that occurs in Fabry disease is associated with progressive proteinuria and a decline in glomerular filtration rate, which over time, leads to end-stage renal disease requiring dialysis and ultimately, kidney transplantation.² Treatment with Elfabrio reduces the accumulation of GL-3 in the kidney (and in other organs), with the goal of stopping or slowing the decline in kidney function.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Elfabrio. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Elfabrio as well as the monitoring required for adverse events and long-term efficacy, approval requires Elfabrio to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

07/03/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Elfabrio is recommended in those who meet the following criteria:

FDA-Approved Indication

24. Fabry Disease. Approve for 1 year if the patient meets ALL of the following (A, B, and C):

- A) The patient is ≥ 18 years of age
- B) The diagnosis is established by ONE of the following (i or ii):
 - i. Patient has a laboratory test demonstrating deficient α -galactosidase A activity in leukocytes or fibroblasts; OR
 - ii. Patient has a molecular genetic test demonstrating a pathogenic variant in the galactosidase alpha (*GLA*) gene; AND
- C) Elfabrio is prescribed by or in consultation with a geneticist, endocrinologist, a metabolic disorder sub-specialist, or a physician who specializes in the treatment of lysosomal storage disorders.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Elfabrio is not recommended in the following situations:

75. Concurrent Use with Galafold (migalastat oral capsules). Galafold has not been evaluated for use in combination with Elfabrio. It is not FDA approved for concurrent use with enzyme replacement therapy.

76. Concurrent Use with Fabrazyme (agalsidase beta intravenous infusion).

77. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Enzyme Replacement Therapy – Fabrazyme Prior Authorization Policy

- Fabrazyme® (agalsidase intravenous infusion – Genzyme)

REVIEW DATE: 04/19/2024

OVERVIEW

Fabrazyme, a human α -galactosidase A (α -Gal), is indicated for **Fabry disease**.¹ It is the same amino acid sequence as the native enzyme and is produced in Chinese hamster ovary cells via recombinant DNA technology. Fabrazyme catalyzes the breakdown of globotriaosylceramide (GL-3) and other α -galactyl-terminated neutral glycosphingolipids to ceramide and galactose and reduces the deposition of GL-3 in the capillary endothelium of the kidney and certain other cell types.

Disease Overview

Fabry disease is a rare inherited X-linked lysosomal storage disorder due to absent or significantly reduced α -Gal activity leading to the accumulation of GL-3 in a wide variety of cells throughout the body.²⁻⁴ The accumulation of GL-3 leads to progressive multisystem disease, primarily impacting the kidney, heart, and nervous system.^{3,4} The incidence of Fabry disease is estimated to be about 1:117,000 live male births.² Fabry disease can be divided into two phenotypes. A severe, classical phenotype typically occurs in men without α -Gal activity, whereas a generally milder non-classical phenotype is found in men and women with some residual α -Gal activity.^{2,3} The diagnosis of Fabry disease can be confirmed in males by demonstrating a deficiency in α -Gal activity, and in all patients by identifying a Fabry disease causing gene mutation.⁴ Long-term consequences of Fabry disease include hypertrophic cardiomyopathy, arrhythmias, renal failure, and stroke.³ The kidney disease that occurs in Fabry disease is associated with progressive proteinuria and a decline in glomerular filtration rate, which over time, leads to end-stage renal disease requiring dialysis and ultimately, kidney transplantation.² Treatment with Fabrazyme reduces the accumulation of GL-3 in the kidney (and in other organs), with the goal of stopping or slowing the decline in kidney function.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Fabrazyme. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Fabrazyme as well as the monitoring required for adverse events and long-term efficacy, approval requires Fabrazyme to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

04/19/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Fabrazyme is recommended in those who meet the following criteria:

FDA-Approved Indication

25. Fabry Disease. Approve for 1 year if the patient meets BOTH of the following (A and B):

- A) The diagnosis is established by ONE of the following (i or ii):
 - i. Patient has a laboratory test demonstrating deficient α -galactosidase A activity in leukocytes or fibroblasts; OR
 - ii. Patient has a molecular genetic test demonstrating a pathogenic variant in the galactosidase alpha (*GLA*) gene; AND
- B) Fabrazyme is prescribed by or in consultation with a geneticist, endocrinologist, a metabolic disorder sub-specialist, or a physician who specializes in the treatment of lysosomal storage disorders.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Fabrazyme is not recommended in the following situations:

78. Concurrent Use with Galafold® (migalastat oral capsules). One small study (n = 23) assessed a single dose of Galafold (150 mg or 450 mg) used concurrently with Fabrazyme or agalsidase alpha.⁵ While a single dose of Galafold significantly increased α -Gal activity, the long-term safety and efficacy of concurrent use of Galafold and Fabrazyme has not been established. Galafold is not FDA approved for concurrent use with Fabrazyme.

79. Concurrent Use with Elfabrio® (pegunigalsidase alfa intravenous infusion).

80. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Enzyme Replacement Therapy – Kanuma Prior Authorization Policy

- Kanuma® (sebelipase alfa intravenous infusion – Alexion)

REVIEW DATE: 04/24/2024

OVERVIEW

Kanuma, a human lysosomal acid lipase (LAL), indicated for the treatment of **LAL deficiency**.¹ It is produced in the egg white of genetically engineered chickens via recombinant DNA technology. LAL catalyzes the breakdown of cholesteryl esters to free cholesterol and fatty acids, and the breakdown of triglycerides to glycerol and free fatty acids.

Disease Overview

LAL deficiency is a rare lysosomal storage disorder characterized by absent or deficient LAL activity leading to the accumulation of cholesterol and triglycerides in the liver and other organs.^{2,3} Patients with LAL deficiency often have dyslipidemias, cardiovascular disease, and progressive liver disease.² The disorder has a heterogeneous presentation ranging from a rapidly progressive form occurring in infants which leads to death in the first year of life, to a childhood/adult-onset form with milder signs and symptoms. Almost all patients with childhood/adult-onset LAL deficiency have hepatomegaly with elevated liver transaminases and have an increased risk of developing fibrosis and cirrhosis.³ The diagnosis of LAL deficiency is established by demonstrating deficient LAL activity in leukocytes, fibroblasts, or liver tissue; or by genetic testing.^{2,3}

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Kanuma. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Kanuma as well as the monitoring required for adverse events and long-term efficacy, approval requires Kanuma to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Kanuma is recommended in those who meet the following criteria:

FDA-Approved Indication

26. Lysosomal Acid Lipase Deficiency. Approve for 1 year if the patient meets BOTH of the following (A and B):

A) The diagnosis is established by ONE of the following (i or ii):

- i.** Patient has a laboratory test demonstrating deficient lysosomal acid lipase activity in leukocytes, fibroblasts, or liver tissue; OR
- ii.** Patient has a molecular genetic test demonstrating biallelic pathogenic or likely pathogenic lysosomal acid lipase (*LAL*) gene variants; AND

04/24/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- B)** Kanuma is prescribed by or in consultation with a geneticist, endocrinologist, a metabolic disorder sub-specialist, or a physician who specializes in the treatment of lysosomal storage disorders.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Kanuma is not recommended in the following situations:

- 81.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Enzyme Replacement Therapy – Lamzede Prior Authorization Policy

- Lamzede® (velmanase alfa-tycv intravenous infusion – Chiesi)

REVIEW DATE: 03/06/2024

OVERVIEW

Lamzede, a recombinant human lysosomal alpha-mannosidase, is indicated for the treatment of **non-central nervous system manifestations of alpha-mannosidosis** in adult and pediatric patients.¹

Disease Overview

Alpha-mannosidosis is an ultra-rare autosomal recessive lysosomal storage disease. It is estimated to occur in 1 to 2:1,000,000 live births.² Alpha-mannosidosis results from reduced activity of the lysosomal enzyme, alpha-mannosidase, which is caused by gene variants in Mannosidase Alpha Class 2B Member 1 (*MAN2B1*). This results in accumulation of mannose-rich oligosaccharides in various tissues, which leads to significant and diverse multi-systemic manifestations. This can include progressive motor function disturbances and physical disability, hearing and speech impairment, intellectual disability, and immune deficiency. Lamzede is the first and only enzyme replacement therapy approved for alpha-mannosidosis in the United States. There are no other FDA approved therapies for alpha-mannosidosis. Treatment is generally targeted towards management of the various clinical manifestations of the disease. Hematopoietic stem cell transplantation (HSCT) has been used to prevent cognitive decline, preserve neurocognitive function, and prevent early death.²⁻⁴ However, not all patients are eligible for HSCT and it is associated with the risk of mortality and complications. Lamzede has been approved by the European Medicines Agency (EMA) in 2018. Diagnosis of alpha-mannosidosis is confirmed by molecular genetic testing and identification of biallelic pathogenic variants in *MAN2B1*. Alpha-mannosidase enzyme activity in peripheral blood leukocytes is 5% to 10% of normal activity in affected individuals.⁵

Clinical Efficacy

The efficacy of Lamzede in adult and pediatric patients with alpha-mannosidosis was established in two pivotal studies (rhLAMAN-05 and rhLAMAN-08) and one non-pivotal trial (rhLAMAN-10).²⁻⁴ Patients with a confirmed diagnosis of alpha-mannosidosis, defined as alpha-mannosidase activity less than 10% of normal activity in blood leukocytes were enrolled. Lamzede demonstrated a statistically significant clearance of serum oligosaccharides vs. placebo in the pivotal trials. Lamzede also demonstrated improvement in endurance, pulmonary function, motor proficiency testing, and a decrease in serum immunoglobulins.

Safety

Lamzede has a Boxed Warning for hypersensitivity reactions, including anaphylaxis.¹ Other Warnings/Precautions for Lamzede include infusion-associated reactions and embryofetal toxicity. Pretreatment with antihistamines, antipyretics, and/or corticosteroids should be considered to reduce the risk of hypersensitivity and infusion-related reactions.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Lamzede. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Lamzede as well as the monitoring required for adverse events and long-

03/06/2024

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

term efficacy, approval requires Lamzede to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Lamzede is recommended in those who meet the following criteria:

FDA-Approved Indication

27. Alpha-mannosidosis. Approve for 1 year if the patient meets ALL of the following (A, B, C, and D):

- A)** Patient has a confirmed diagnosis of alpha-mannosidosis, defined as alpha-mannosidase activity less than 10% of normal activity in blood leukocytes; AND
- B)** Patient has biallelic pathogenic variants in Mannosidase Alpha Class 2B Member 1 (*MAN2B1*) as confirmed by mutation testing; AND
- C)** Patient has non-central nervous system manifestations; AND
Note: Examples of non-central nervous system manifestations include progressive motor function disturbances, physical disability, hearing and speech impairment, skeletal abnormalities, and immune deficiency.
- D)** The medication is prescribed by or in consultation with a geneticist, endocrinologist, a metabolic disorder sub-specialist, or a physician who specializes in the treatment of lysosomal storage disorders.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Lamzede is not recommended in the following situations:

- 82.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Enzyme Replacement Therapy – Mepsevii Prior Authorization Policy

- Mepsevii® (vestronidase alfa-vjbk intravenous infusion – Ultragenyx)

REVIEW DATE: 04/24/2024

OVERVIEW

Mepsevii, a lysosomal beta glucuronidase (GUS), is indicated for the treatment of **Mucopolysaccharidosis type VII** [MPS VII], Sly syndrome).¹ It is produced in a Chinese hamster ovary cell line via recombinant DNA technology. It has the same amino acid sequence as human GUS and catabolizes accumulated glycosaminoglycans in lysosomes in affected tissues.

Disease Overview

MPS VII or Sly syndrome is an extremely rare lysosomal storage disorder characterized by deficient GUS activity.² In MPS VII, the partially catabolized glycosaminoglycans, chondroitin sulfate, dermatan sulfate, and heparin sulfate accumulate in the lysosomes, ultimately leading to the signs and symptoms of the disease.^{2,3} The onset, severity, and rate of progression of MPS VII is heterogeneous. Patients may present at birth with hydrops fetalis and only survive a few months while others may have milder disease and survive into their 40s.² However, most patients have mental retardation, hepatosplenomegaly, and musculoskeletal issues including short stature, coarse facial features, loss of range of motion, restricted mobility, scoliosis, and kyphosis. The diagnosis of MPS VII is established by demonstrating deficient GUS activity in leukocytes, fibroblasts, or serum; or by genetic testing.³ Treatment for MPS VII includes enzyme replacement therapy with Mepsevii and hematopoietic stem cell transplantation.²

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Mepsevii. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Mepsevii as well as the monitoring required for adverse events and long-term efficacy, approval requires Mepsevii to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

04/24/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Mepsevii is recommended in those who meet the following criteria:

FDA-Approved Indication

28. Mucopolysaccharidosis Type VII (Sly Syndrome). Approve for 1 year if the patient meets BOTH of the following (A and B):

A) The diagnosis is established by ONE of the following (i or ii):

- i.** Patient has a laboratory test demonstrating deficient beta-glucuronidase activity in leukocytes, fibroblasts, or serum; OR
- ii.** Patient has a molecular genetic test demonstrating biallelic pathogenic or likely pathogenic glucuronidase (*GUS*) gene variants; AND

B) Mepsevii is prescribed by or in consultation with a geneticist, endocrinologist, a metabolic disorder sub-specialist, or a physician who specializes in the treatment of lysosomal storage disorders.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Mepsevii is not recommended in the following situations:

83. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

REFERENCES

- 302. Mepsevii® intravenous infusion [prescribing information]. Novato, CA: Ultragenyx; December 2020.
- 303. Montano AM, Lock-Hock N, Steiner RD, et al. Clinical course of sly syndrome (mucopolysaccharidosis type VII). *J Med Genet.* 2016;53:403-418.

PRIOR AUTHORIZATION POLICY

POLICY: Enzyme Replacement Therapy – Naglazyme Prior Authorization Policy

- Naglazyme® (galsulfase intravenous infusion – BioMarin)

REVIEW DATE: 04/24/2024

OVERVIEW

Naglazyme, a human *N*-acetylgalactosamine 4-sulfatase, is indicated for **Mucopolysaccharidosis type VI** (Maroteaux – Lamy syndrome [MPS VI]).¹ It is produced in a Chinese hamster ovary cell line via recombinant DNA technology. The enzyme catalyzes the hydrolysis of the sulfate ester from the glycosaminoglycans, chondroitin 4-sulfate and dermatan sulfate. Naglazyme has been shown to improve walking and stair climbing capacity.

Disease Overview

MPS VI, or Maroteaux – Lamy syndrome, is a rare lysosomal storage disorder characterized by a deficiency of *N*-acetylgalactosamine 4-sulfatase (arylsulfatase B).^{2,3} The enzyme deficiency results in the accumulation of partially hydrolyzed dermatan sulfate and chondroitin 4-sulfate in lysosomes leading to the signs and symptoms of the disease.^{2,3} The onset, severity, and rate of progression of MPS VI is heterogeneous; however, most patients are severely affected with a rapidly progressive form.³ Clinical manifestations include coarse facial features, short stature, kyphoscoliosis, joint stiffness, pulmonary insufficiency, cardiac disease, hepatosplenomegaly, corneal clouding, and hernias.^{2,3} The definitive diagnosis of MPS VI is established by demonstrating deficient arylsulfatase B enzyme activity in leukocytes or fibroblasts; or by genetic testing.^{2,3} Definitive treatment of MPS VI consists of either enzyme replacement therapy with Naglazyme or hematopoietic stem cell transplantation. Due to the morbidity and mortality associated with hematopoietic stem cell transplantation, this therapy is typically reserved for patients who are intolerant of or do not respond to enzyme replacement therapy.²

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Naglazyme. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Naglazyme as well as the monitoring required for adverse events and long-term efficacy, approval requires Naglazyme to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Naglazyme is recommended in those who meet the following criteria:

FDA-Approved Indication

29. Mucopolysaccharidosis Type VI (Maroteaux – Lamy Syndrome). Approve for 1 year if the patient meets BOTH of the following (A and B):

A) The diagnosis is established by ONE of the following (i or ii):

- i.** Patient has a laboratory test demonstrating deficient *N*-acetylgalactosamine 4-sulfatase (arylsulfatase B) activity in leukocytes or fibroblasts; OR
- ii.** Patient has a molecular genetic test demonstrating biallelic pathogenic or likely pathogenic arylsulfatase B (*ARSB*) gene variants; AND

B) Naglazyme is prescribed by or in consultation with a geneticist, endocrinologist, a metabolic disorder sub-specialist, or a physician who specializes in the treatment of lysosomal storage disorders.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Naglazyme is not recommended in the following situations:

84. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Enzyme Replacement Therapy – Revcovi Prior Authorization Policy

- Revcovi® (elapegademase-lvlr intramuscular injection – Chiesi)

REVIEW DATE: 12/11/2024

OVERVIEW

Revcovi, a recombinant adenosine deaminase, is indicated for the treatment of **adenosine deaminase severe combined immune deficiency (ADA-SCID)** in pediatric and adult patients.¹

Disease Overview

ADA-SCID is an ultra-rare, autosomal recessive genetic disorder of purine metabolism affecting lymphocyte development, viability, and function.^{1,2} It is estimated to occur in 1:200,000 to 1:1,000,000 live births. ADA is a purine salvage enzyme which metabolizes deoxyadenosine (dAdo) and adenosine (Ado) into deoxyinosine and inosine, respectively.³ When ADA is deficient, dAdo accumulates in intracellular and extracellular compartments, along with its metabolite, deoxyadenosinetriphosphate (dATP). The buildup of both dAdo and dATP negatively impacts lymphocyte development and function by impeding DNA replication and repair, inducing apoptosis, and inhibiting lymphocyte activation.

There are a variety of phenotypes of ADA deficiency; ADA-SCID is the most severe and typically diagnosed before 1 year of age.² Infants with typical ADA-SCID have failure to thrive and opportunistic infections associated with marked depletion of B, T, and NK lymphocytes. Manifestations include persistent diarrhea, extensive dermatitis, recurrent pneumonia, and other life-threatening illnesses caused by opportunistic infections. Growth failure and other physical manifestations, including hepatic and neurologic abnormalities, may also be present. Without treatment, patients with ADA-SCID rarely survive beyond 1 to 2 years of age.

Guidelines

According to a consensus statement for management of ADA-SCID (2018) and updated guidelines in 2023, diagnosis is usually established by demonstrating absent or very low (< 1 % of normal) ADA catalytic activity, accompanied by elevated Ado or dAdo in plasma, urine, or dried blood spots.^{3,4} This should be followed by genetic testing to confirm bi-allelic mutations in the *ADA* gene. Enzyme replacement therapy (ERT) is recommended by the consensus panel for all patients newly diagnosed with ADA-SCID as an immediate stabilizing measure. The ideal duration of ERT has not been established. The consensus recommends that most patients use ERT as a “bridge” for a few months to approximately 2 years, prior to undergoing curative therapy with a hematopoietic stem cell transplant (HSCT) or hematopoietic stem cell gene therapy. Long-term use of ERT has declined in the past 30 years and has not been systematically studied. Lymphocyte counts and function may deteriorate over time, contributing to increased risk of infections and malignancy. Therefore, ERT longer than 5 to 8 years should be avoided and employed on a continuous basis only when neither HSCT nor gene therapy have been available or effective. The consensus also suggests ERT use for patients with later-onset phenotypes who may not be ideal candidates for curative processes.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Revcovi. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Revcovi, approval requires it to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Revcovi is recommended in those who meet the following criteria:

FDA-Approved Indication

3. **Adenosine Deaminase Severe Combined Immunodeficiency (ADA-SCID).** Approve for 1 year if the patient meets BOTH of the following (A and B):
 - A) Patient has a diagnosis of ADA-SCID confirmed by ONE of the following (i or ii):
 - i. At baseline (i.e., prior to initiating enzyme replacement therapy), the patient has had absent or very low (< 1% of normal) adenosine deaminase (ADA) catalytic activity; OR
 - ii. Patient has had molecular genetic testing confirming bi-allelic pathogenic variants in the *ADA* gene; AND
 - B) The medication is prescribed by or in consultation with an immunologist, hematologist/oncologist, or physician that specializes in ADA-SCID or related disorders.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Revcovi is not recommended in the following situations:

5. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Enzyme Replacement Therapy – Strensiq Prior Authorization Policy

- Strensiq® (asfotase alfa subcutaneous injection – Alexion)

REVIEW DATE: 07/31/2024

OVERVIEW

Strensiq, a tissue non-specific alkaline phosphatase (TNSALP), is indicated for the treatment of patients with **perinatal/infantile- and juvenile-onset hypophosphatasia (HPP)**.¹ Strensiq is an enzyme replacement therapy which replaces human TNSALP.

Disease Overview

HPP is an inherited metabolic disease caused by a loss-of-function pathogenic variant in the gene which codes for TNSALP.² TNSALP is tissue-bound and expressed in high concentrations in the liver, kidney, neurons, neutrophils, bone, and teeth.^{2,3} In HPP, inorganic pyrophosphate and pyridoxal 5'-phosphate, substrates for TNSALP, are increased and lead to disease manifestations. Inorganic pyrophosphate is an inhibitor of bone mineralization, and its accumulation leads to rickets and osteomalacia. Pyridoxal 5'-phosphate, a derivative of vitamin B₆, is necessary for the synthesis of gamma aminobutyric acid (GABA). However, for pyridoxal 5'-phosphate to enter the neuron, it must be dephosphorylated to allow pyridoxal to enter the neuron where it is rephosphorylated. The decreased synthesis of GABA in HPP leads to seizures.

HPP is a rare disease, with an estimated live-birth incidence, for the severe forms of HPP, of 1:100,000 in Canada and approximately 1:300,000 in Europe.^{2,4} Prevalence in certain populations, such as Canadian Mennonites, may be as high as 1:2,500 births. Disease severity can range from neonatal death with almost no skeletal mineralization to dental problems in adults without any bone symptoms.²⁻⁴ In patients most severely affected by HPP, mortality ranges from 50% to nearly 100% during infancy.²

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Strensiq. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Strensiq as well as the monitoring required for adverse events and long-term efficacy, approval requires Strensiq to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Strensiq is recommended in those who meet the following criteria:

FDA-Approved Indication

- 35. Hypophosphatasia – Perinatal/Infantile- and Juvenile-Onset.** Approve for 1 year if the patient meets ALL of the following (A, B, C, and D):
- 10.** Diagnosis is supported by ONE of the following (i, ii, or iii):

07/31/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- i. Molecular genetic testing documenting pathogenic tissue non-specific alkaline phosphatase (*ALPL*) gene variants; OR
 - ii. Low baseline serum alkaline phosphatase activity; OR
 - iii. An elevated level of a tissue non-specific alkaline phosphatase substrate (i.e., serum pyridoxal 5'-phosphate, serum or urinary inorganic pyrophosphate, urinary phosphoethanolamine); AND
11. Patient meets ONE of the following (i or ii):
- i. Patient currently has, or has a history of, clinical manifestations consistent with hypophosphatasia; OR
Note: Examples of clinical manifestations include skeletal abnormalities, premature tooth loss, muscle weakness, poor feeding, failure to thrive, respiratory problems, vitamin B₆-dependent seizures.
 - ii. Patient has a family (parent or sibling) of hypophosphatasia without current clinical manifestations of hypophosphatasia; AND
12. Disease onset $\leq$ 18 years of age; AND
13. Strensiq is prescribed by or in consultation with a geneticist, endocrinologist, a metabolic disorder sub-specialist, or a physician who specializes in the treatment of hypophosphatasia or related disorders.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Strensiq is not recommended in the following situations:

- 8. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Enzyme Replacement Therapy – Sucraid Prior Authorization Policy

- Sucraid® (sacrosidase oral solution – QOL Medical)

REVIEW DATE: 04/19/2024

OVERVIEW

Sucraid, an enzyme replacement therapy, is indicated for the treatment of genetically determined sucrase deficiency, which is part of **congenital sucrase-isomaltase deficiency (CSID)**.¹

Disease Overview

CSID is an autosomal recessive intestinal disorder characterized by reduced or absent activity of the sucrase-isomaltase complex.^{2,3} These enzymes are responsible for the hydrolysis of complex sugars and starches into simple sugars which are absorbed from the gastrointestinal tract. With absent or diminished enzyme activity, complex sugars and starches accumulate in the small intestine and lead to disease manifestations.² Symptoms include osmotic diarrhea, vomiting, bloating, abdominal pain, and steatorrhea.^{2,3} Patients can occasionally experience dehydration, failure to thrive, developmental delay, and muscular hypotonia.² The diagnosis of CSID can be established by testing small intestine biopsy specimens for reduced or absent enzyme activity or by genetic testing to identify a mutation in the sucrase-isomaltase gene.³⁻⁵

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Sucraid. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Sucraid as well as the monitoring required for adverse events and long-term efficacy, approval requires Sucraid to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Sucraid is recommended in those who meet the following criteria:

FDA-Approved Indication

30. Congenital Sucrase-Isomaltase Deficiency. Approve for 1 year if the patient meets ALL of the following (A, B, and C):

A) The diagnosis is established by ONE of the following (i or ii):

- i.** Patient has endoscopic biopsy of the small bowel with disaccharidase levels consistent with congenital sucrase-isomaltase deficiency as evidenced by ALL of the following (a, b, c, and d):
 - a)** Decreased (usually absent) sucrase level (normal reference: > 25 U/g protein); AND
 - b)** Decreased or normal isomaltase (palatinase) level [normal reference: > 5 U/g protein]; AND
 - c)** Decreased maltase level (normal reference: > 100 U/g protein); AND

04/19/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- d) Decreased or normal lactase level (normal reference: > 15 U/g protein); OR
- ii. Patient has a molecular genetic test demonstrating homozygous or compound heterozygous pathogenic or likely pathogenic sucrase-isomaltase gene variant; AND
- B) Prior to starting therapy with Sucraid, patient had symptomatic congenital sucrose-isomaltase deficiency (e.g., diarrhea, bloating, abdominal cramping); AND
- C) The medication is prescribed by or in consultation with a geneticist, gastroenterologist, a metabolic disorder sub-specialist, or a physician who specializes in the treatment of congenital diarrheal disorders.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Sucraid is not recommended in the following situations:

- 85. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Enzyme Replacement Therapy – Vimizim Prior Authorization Policy

- Vimizim® (elosulfase alfa intravenous infusion – BioMarin)

REVIEW DATE: 04/24/2024

OVERVIEW

Vimizim, a human *N*-acetylgalactosamine-6-sulfatase, is indicated for **Mucopolysaccharidosis type IVA** (Morquio A syndrome [MPS IVA]).¹ It is produced in Chinese hamster ovary cells via recombinant DNA technology. Vimizim is a hydrolytic lysosomal enzyme which is taken up by lysosomes and hydrolyzes sulfate from the non-reduced ends of the glycosaminoglycans keratan sulfate and chondroitin-6-sulfate.

Disease Overview

MPS IVA (Morquio A syndrome) is a rare lysosomal storage disorder characterized by deficient *N*-acetylgalactosamine-6-sulfatase activity leading to the accumulation of chondroitin-6-sulfate and keratan sulfate in lysosomes in bone, cartilage, and ligaments.^{2,3} The clinical course, onset, and severity of MPS IVA is heterogeneous.² Manifestations of MPS IVA include short trunk dwarfism with short neck, kyphoscoliosis, odontoid dysplasia, knock-knee, cervical spinal cord compression, hypermobile joints, cardiac disease, respiratory insufficiency, obstructive sleep apnea, corneal clouding, and dental abnormalities.²⁻⁴ MPS IVA has not been associated with cognitive decline.² The definitive diagnosis of MPS IVA is established by demonstrating deficient *N*-acetylgalactosamine-6-sulfatase activity in leukocytes or fibroblasts; or by genetic testing.² Definitive treatment for MPS IVA consists of enzyme replacement therapy with Vimizim. Hematopoietic stem cell transplantation is not recommended for MPS IVA.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Vimizim. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Vimizim as well as the monitoring required for adverse events and long-term efficacy, approval requires Vimizim to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Vimizim is recommended in those who meet the following criteria:

FDA-Approved Indication

31. Mucopolysaccharidosis Type IVA (Morquio A Syndrome). Approve for 1 year if the patient meets BOTH of the following (A and B):

A) The diagnosis is established by ONE of the following (i or ii):

- i. Patient has a laboratory test demonstrating deficient *N*-acetylgalactosamine-6-sulfatase activity in leukocytes or fibroblasts; OR

04/24/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- ii. Patient has a molecular genetic test demonstrating biallelic pathogenic or likely pathogenic *N*-acetylgalactosamine-6-sulfatase (*GALNS*) gene variants; AND
- B) Vimizim is prescribed by or in consultation with a geneticist, endocrinologist, a metabolic disorder sub-specialist, or a physician who specializes in the treatment of lysosomal storage disorders.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Vimizim is not recommended in the following situations:

- 86. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Enzyme Replacement Therapy – Xenpozyme Prior Authorization Policy

- Xenpozyme™ (olipudase alfa-rpcp intravenous infusion – Genzyme)

REVIEW DATE: 09/25/2024

OVERVIEW

Xenpozyme, a hydrolytic lysosomal sphingomyelin-specific enzyme, is indicated for the treatment of **non-central nervous system (CNS) manifestations of acid sphingomyelinase deficiency (ASMD)** in adults and pediatric patients.¹

Disease Overview

ASMD is an autosomal recessive lysosomal storage disease that results from reduced activity of the enzyme acid sphingomyelinase (ASM), caused by pathogenic variants in the sphingomyelin phosphodiesterase 1 gene.^{1,2} ASM degrades sphingomyelin to ceramide and phosphocholine.¹ The deficiency of ASM causes an intra-lysosomal accumulation of sphingomyelin (as well as cholesterol and other cell membrane lipids) in various tissues. Xenpozyme provides an exogenous source of ASM. Xenpozyme is not expected to cross the blood-brain barrier or modulate the CNS manifestations of ASMD.

ASMD has historically been known as Niemann-Pick disease type A and/or B and is associated with a spectrum of disease phenotypes.² ASMD type B (also known as chronic visceral ASMD or Niemann-Pick type B disease) and ASMD type A/B (chronic neurovisceral ASMD, Niemann-Pick disease type A/B, or intermediate phenotype) have disease onset from childhood to early adulthood. ASMD type B has minimal to no CNS involvement, while ASMD type A/B has less severe neurologic manifestations than those observed in ASMD type A, which is fatal in early childhood. Visceral manifestations in ASMD include interstitial lung disease with decreased diffusing capacity of the lung, hepatosplenomegaly, progressive liver disease with cirrhosis or fibrosis, dyslipidemia, osteopenia, and thrombocytopenia. The leading causes of early mortality in adults with ASMD are lung disease/infections, liver failure, and bleeding.

Clinical Efficacy

The efficacy of Xenpozyme in adults and pediatric patients with ASMD was established in two pivotal trials (ASCEND and ASCEND-PEDS, respectively).^{2,3} The pivotal trials enrolled patients with ASMD types B or A/B, but not type A. Eligible patients also had splenomegaly (spleen volumes ≥ 5 multiples of normal [MN] in pediatric patients and ≥ 6 MN in adults). In adults and children, Xenpozyme treatment improved spleen and liver volume as well as diffusing capacity of the lungs for carbon monoxide.

Guidelines

A consensus guideline for ASMD diagnosis has been developed by an international expert panel.⁴ When there is a suspicion of ASMD, an ASM enzyme assay should be performed followed by gene sequencing if the enzymatic test is indicative of ASMD. Whenever possible, an enzyme assay for ASM and glucocerebrosidase activity should be performed in parallel to distinguish ASMD from Gaucher disease. Gene sequencing can be conducted after diagnosis based on ASM activity, but is not diagnostic on its own because of the high number of genetic variants of unknown significance. Biomarkers, while useful in disease monitoring, should not be considered sufficient for ASMD diagnosis (i.e., these include plasma chitotriosidase, plasma lyso-sphingolipids, and oxysterols). Physicians should perform clinical assessments to predict the phenotype and clinical course of the disease upon identification of sphingomyelin phosphodiesterase-1 (SMPD1) pathogenic variants of unknown pathogenicity in pediatric patients.

09/25/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Safety

Xenpozyme has a Boxed Warning for hypersensitivity reactions, including anaphylaxis.¹ Prior to administration, pretreatment with antihistamines, antipyretics, and/or corticosteroids should be considered and appropriate medical measures, including cardiopulmonary resuscitation equipment should be readily available during Xenpozyme administration.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Xenpozyme. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Xenpozyme as well as the monitoring required for adverse events and long-term efficacy, approval requires Xenpozyme to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Xenpozyme is recommended in those who meet the following criteria:

FDA-Approved Indication

32. Acid Sphingomyelinase Deficiency (ASMD). Approve for 1 year if the patient meets ALL of the following (A, B, C, and D):

Note: ASMD has historically been known as Niemann-Pick Disease Type A and/or B.

A) The diagnosis of ASMD meets ALL of the following (i, ii, and iii):

- i.** The diagnosis of ASMD has been established by acid sphingomyelinase (ASM) enzymatic assay testing; AND
- ii.** The diagnosis of ASMD has been confirmed by genetic testing demonstrating biallelic pathogenic variants in the sphingomyelin phosphodiesterase-1(*SMPD1*) gene; AND
- iii.** A diagnosis of Gaucher disease has been excluded; AND

B) Patient meets ONE of the following (i or ii):

- i.** Patient has ASMD type B; OR
- ii.** Patient has ASMD type A/B; AND

C) According to the prescriber, patient has two or more non-central nervous system signs of ASMD type B or type A/B; AND

Note: Examples of non-central nervous system signs of ASMD type B or type A/B include but are not limited to hepatosplenomegaly, interstitial lung disease, decreased diffusing capacity of the lungs, progressive liver disease with cirrhosis or fibrosis, dyslipidemia, osteopenia, thrombocytopenia, anemia, leukopenia.

D) The medication is prescribed by or in consultation with a geneticist, endocrinologist, a metabolic disorder sub-specialist, or a physician who specializes in the treatment of lysosomal storage disorders.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Xenpozyme is not recommended in the following situations:

- 87. Acid Sphingomyelinase Deficiency (ASMD), Type A.** Xenpozyme is indicated for non-central nervous system manifestations of ASMD. Xenpozyme is not expected to cross the blood-brain barrier or modulate the central nervous system manifestations of ASMD.¹ Patients with ASMD type A were excluded from the pivotal trials with Xenpozyme.^{2,3}
- 88.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

- POLICY:** Erectile Dysfunction – Alprostadil Products Prior Authorization Policy
- Caverject® (alprostadil intracavernosal injection – Pfizer)
 - Caverject Impulse® (alprostadil intracavernosal injection – Pfizer)
 - Edex® (alprostadil intracavernosal injection – Endo)
 - MUSE® (alprostadil urethral suppository – MEDA)

REVIEW DATE: 11/06/2024

OVERVIEW

Caverject, Caverject Impulse, Edex, and Muse are indicated for the treatment of **erectile dysfunction** due to neurogenic, vasculogenic, psychogenic, or mixed etiology.¹⁻⁴ Additionally, Caverject may be used as an adjunct to other diagnostic tests in the diagnosis of erectile dysfunction.¹ Injectable alprostadil products include Caverject, Caverject Impulse (disposable, single-dose, dual chamber syringe system), and Edex.¹⁻³ MUSE is available as a single-use, medicated transurethral system for the delivery of alprostadil directly in the urethra.⁴ MUSE is administered by inserting the applicator stem into the urethra after urination.¹

These products have also been studied for penile rehabilitation.⁵ Alprostadil may help the recovery of erectile function by promotion of cavernosal oxygenation levels. Several studies have demonstrated the efficacy of alprostadil injections and MUSE for early penile rehabilitation post-radical prostatectomy.⁶⁻¹²

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of alprostadil products given as an intracavernosal injection or as a urethral suppository. Alprostadil products given by intravenous (IV) or other routes of administration is not covered by this policy. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with alprostadil products as well as the monitoring required for adverse events and long-term efficacy, some approvals require the alprostadil products to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of alprostadil products is recommended in those who meet one of the following criteria:

FDA-Approved Indication

36. Erectile Dysfunction. Approve for 1 year.

11/06/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Other Uses with Supportive Evidence

37. of Radical Prostatectomy. Approve for 1 year if patient meets BOTH of the following (A and B):

A. Patient was started on therapy post-operatively; AND

B. Patient is currently continuing therapy with an alprostadil product.

Note: Alprostadil products for post-radical prostatectomy are Caverject, Caverject Impulse, Edex, and MUSE.

38. Prophylaxis after Radical Prostatectomy (Early Penile Rehabilitation). Approve for 1 year if the patient meets ALL of the following (A, B, and C).

A) Patient is treatment-naïve; AND

B) Therapy will be started within 6 months of surgery; AND

C) The medication is prescribed by or in consultation with a urologist

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of alprostadil products is not recommended in the following situations:

9. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Erectile Dysfunction – Avanafil Prior Authorization Policy

- Stendra™ (avanafil tablets – Mist Pharmaceuticals, generic)

REVIEW DATE: 11/06/2024

OVERVIEW

Avanafil (Stendra, generic), a phosphodiesterase type 5 (PDE5) inhibitor, is indicated for the treatment of **erectile dysfunction**.¹

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Avanafil. All approvals are provided for the duration noted below.

Automation: When available, the ICD-10 codes for male erectile dysfunction (ICD-10: N52.*) will be used for automation to allow approval of the requested medication. This automation is gender-selective and is not applicable for women; approval for use in women is always determined by prior authorization criteria.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Avanafil is recommended in those who meet the following criteria:

FDA-Approved Indications

25. Erectile Dysfunction. Approve for 1 year.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Avanafil is not recommended in the following situations:

10. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Erectile Dysfunction – Sildenafil Prior Authorization Policy

- Viagra® (sildenafil tablets – Pfizer, generic)

REVIEW DATE: 11/06/2024

OVERVIEW

Sildenafil (Viagra, generic), a phosphodiesterase type 5 (PDE5) inhibitor, is indicated for the treatment of **erectile dysfunction**.¹

Sildenafil has been studied for other indications.

- **Benign Prostatic Hyperplasia.** The European Association of Urology guidelines (2022) note that phosphodiesterase type 5 inhibitors can be used in men with moderate-to-severe lower urinary tract symptoms with or without erectile dysfunction.⁹ The guidelines add that based on the results from a meta-analysis⁸, younger men with lower body mass index and more severe lower urinary tract symptoms benefit the most from phosphodiesterase type 5 inhibitors.
- **High-Altitude Pulmonary Edema.** Published guidelines for the prevention of high-altitude pulmonary edema recommend nifedipine as the preferred pharmacologic treatment option.¹² Other pharmacologic therapies include salmeterol, tadalafil, sildenafil, dexamethasone, or acetazolamide.
- **Prophylaxis after Radical Prostatectomy.** Viagra given on a daily basis has been used to improve the return of normal spontaneous erectile function, improve tissue oxygenation, and prevent penile fibrosis after nerve-sparing radical prostatectomy.^{10,11} It is better to initiate a penile rehabilitation program as soon as possible after surgery in order to limit and prevent postoperative local hypoxiation and fibrosis.
- **Pulmonary Arterial Hypertension.** Sildenafil tablets (Revatio®) are approved for pulmonary arterial hypertension.² Sildenafil (Viagra, generics) are available in 25 mg, 50 mg, and 100 mg tablets, and Revatio is available as 20 mg tablets. Viagra has been used for this diagnosis.^{3,4} Doses of Viagra that were used in these reports ranged from 25 mg twice daily to 100 mg five times daily. Patients will have usually been started on Revatio 20 mg three times daily.
- **Raynaud's Phenomenon.** There are studies which show sildenafil has been beneficial in patients with Raynauds's phenomenon.^{5,6} Guidelines from the European League against Rheumatism (EULAR) on the treatment of systemic sclerosis (2023) recommend considering dihydropyridine calcium channel blockers (CCBs), usually oral nifedipine, for first-line therapy of Raynaud's phenomenon in patients with systemic sclerosis.⁷ Phosphodiesterase type 5 inhibitors should also be considered in such clinical scenarios.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of sildenafil. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with sildenafil as well as the monitoring required for adverse events and long-term efficacy, some approvals require sildenafil to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: When available, the ICD-10 codes for male erectile dysfunction (ICD-10: N52.*) will be used for automation to allow approval of the requested medication. This automation is gender-selective

11/06/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

and is not applicable for women; approval for use in women is always determined by prior authorization criteria.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of sildenafil is recommended in those who meet one of the following criteria:

FDA-Approved Indications

1. **Erectile Dysfunction.** Approve for 1 year.

Other Uses with Supportive Evidence

2. **Benign Prostatic Hyperplasia.** Approve for 1 year if the patient meets ONE of the following (A or B):

Note: For men with erectile dysfunction and benign prostatic hyperplasia, use criterion 1 above.

3. Patient has tried an alpha-1 (α 1) blocker; OR

Note: Examples of alpha-1 (α 1) blockers include doxazosin, terazosin, tamsulosin, alfuzosin.

4. Patient has tried a 5 α -reductase inhibitor.

Note: Examples of a 5 α -reductase inhibitor includes finasteride, dutasteride.

5. **High-Altitude Pulmonary Edema (HAPE), Treatment or Prevention.** Approve for 1 year in patients who meet BOTH of the following (A and B):

A) Patient has HAPE or a of HAPE; AND

B) Patient has tried one other pharmacologic therapy for the treatment or prevention of HAPE.

Note: Examples of other pharmacologic therapy for the treatment of HAPE are nifedipine, Serevent (salmeterol inhalation powder), dexamethasone, acetazolamide, Cialis (tadalafil tablets).

6. **Prophylaxis After Radical Prostatectomy (Early Penile Rehabilitation).** Approve for 1 year in patients who meet BOTH of the following (A and B):

A) Patient had radical prostatectomy within the previous 12 months; AND

B) The medication is prescribed by or in consultation with a urologist.

7. **Pulmonary Arterial Hypertension.** Approve for 1 year.

8. **Raynaud's Phenomenon.** Approve for 1 year if the patient meets ONE of the following (A or B):

9. Patient has tried one calcium channel blocker; OR

Note: Examples of calcium channel blockers include amlodipine, felodipine, nifedipine.

B) According to the prescriber, use of a calcium channel blocker is contraindicated.

Note: Examples of reasons a patient cannot take calcium channel blocker therapy include right heart failure or decreased cardiac output.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of sildenafil is not recommended in the following situations:

1. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Erectile Dysfunction – Tadalafil Prior Authorization Policy

- Cialis® (tadalafil tablets – Eli Lilly, generic)

REVIEW DATE: 11/06/2024

OVERVIEW

Tadalafil (Cialis, generic), a phosphodiesterase type 5 (PDE5) inhibitor, is indicated for the following uses¹:

- **Benign prostatic hyperplasia.**
- **Erectile dysfunction.**
- **Erectile dysfunction and the signs and symptoms of benign prostatic hyperplasia.**

Tadalafil has been studied for other indications:

- **High-Altitude pulmonary edema.** Published guidelines for the prevention of high-altitude pulmonary edema recommend nifedipine as the preferred pharmacologic treatment option.¹¹ Other pharmacologic therapies include salmeterol, sildenafil, dexamethasone, or acetazolamide.
- **Prophylaxis after radical prostatectomy.** Multiple studies have evaluated the efficacy of tadalafil for prophylaxis after radical prostatectomy.⁵⁻⁷
- **Pulmonary arterial hypertension.** Adcirca® (tadalafil tablets, generic) contain the same active ingredient as tadalafil (Cialis, generic) and is indicated for the treatment of pulmonary arterial hypertension. Tadalafil (Cialis, generic) is available in 2.5 mg, 5 mg, 10 mg, and 20 mg tablets. Adcirca is available as a 20 mg tablet. Tadalafil (Cialis, generic) has been used in multiple studies for pulmonary arterial hypertension.⁸⁻¹⁰
- **Raynaud's phenomenon.** There are studies which show tadalafil has been beneficial in patients with Raynaud's phenomenon.^{2,3} Guidelines from the European League against Rheumatism (EULAR) on the treatment of systemic sclerosis (2023) recommend considering dihydropyridine calcium channel blockers (CCBs), usually oral nifedipine, for first-line therapy of Raynaud's phenomenon in patients with systemic sclerosis.⁴ Phosphodiesterase type 5 inhibitors should also be considered in such clinical scenarios.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of tadalafil. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with tadalafil as well as the monitoring required for adverse events and long-term efficacy, some approvals require tadalafil to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: When available, the ICD-10 codes for male erectile dysfunction (ICD-10: N52.*) will be used for automation to allow approval of the requested medication. This automation is gender-selective and is not applicable for women; approval for use in women is always determined by prior authorization criteria.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of tadalafil is recommended in those who meet one of the following criteria:

11/06/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

FDA-Approved Indications

10. Benign Prostatic Hyperplasia. Approve for 1 year if the patient meets ONE of the following (A or B):

Note: For men with erectile dysfunction and benign prostatic hyperplasia, use criterion 2 below.

A) Patient has tried an alpha-1 (α 1) blocker; OR

Note: Examples of alpha-1 (α 1) blockers include doxazosin, terazosin, tamsulosin, alfuzosin.

B) Patient has tried a 5 α -reductase inhibitor.

Note: Examples of 5 α -reductase inhibitor includes finasteride, dutasteride.

11. Erectile Dysfunction. Approve for 1 year.

Other Uses with Supportive Evidence

12. High-Altitude Pulmonary Edema (HAPE), Treatment or Prevention. Approve for 1 year in patients who meet BOTH of the following (A and B):

A) Patient has HAPE or a history of HAPE; AND

B) Patient has tried one other pharmacologic therapy for treatment or prevention of HAPE.

Note: Examples of other pharmacologic therapy for the treatment of HAPE are nifedipine, Serevent (salmeterol inhalation powder), dexamethasone, acetazolamide, sildenafil.

13. Prophylaxis After Radical Prostatectomy (Early Penile Rehabilitation). Approve for 1 year in patients who meet BOTH of the following (A and B):

A) Patient had radical prostatectomy within the previous 12 months; AND

B) The medication is prescribed by or in consultation with an urologist.

14. Pulmonary Arterial Hypertension (PAH). Approve for 1 year in patients who cannot use Adcirca (tadalafil tablets, generic) because the dose is not available using Adcirca (tadalafil tablets, generic), that is, patients who are using 10 mg doses of tadalafil (Cialis, generic).

Note: Patients using 20 mg or 40 mg of tadalafil (Cialis, generic) for PAH should use Adcirca (tadalafil tablets, generic).

15. Raynaud's Phenomenon. Approve for 1 year if the patient meets ONE of the following (A or B):

A) Patient has tried one calcium channel blocker; OR

Note: Examples of calcium channel blockers include amlodipine, felodipine, nifedipine.

B) According to the prescriber, use of a calcium channel blocker is contraindicated.

Note: Examples of reasons a patient cannot take calcium channel blocker therapy include right heart failure or decreased cardiac output.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of tadalafil is not recommended in the following situations:

1. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

- POLICY:** Erectile Dysfunction – Vardenafil Prior Authorization Policy
- Levitra® (vardenafil tablets – GlaxoSmithKline, generic)
 - Staxyn™ (vardenafil orally disintegrating tablet – GlaxoSmithKline, generic)

REVIEW DATE: 11/06/2024

OVERVIEW

Vardenafil tablets (Levitra, generic) and vardenafil orally disintegrating tablets (Staxyn, generic), phosphodiesterase type 5 inhibitors, are indicated for the treatment of **erectile dysfunction**.^{1,2}

Vardenafil has been studied for other indications:

- **Benign Prostatic Hyperplasia.** Vardenafil has been studied in benign prostatic hyperplasia.^{5,6} The European Association of Urology guidelines (2022) note that phosphodiesterase type 5 inhibitors can be used in men with moderate-to-severe lower urinary tract symptoms with or without erectile dysfunction.⁷ The guidelines add that based on the results from a meta-analysis⁸, younger men with lower body mass index and more severe lower urinary tract symptoms benefit the most from treatment with phosphodiesterase type 5 inhibitors.
- **Prophylaxis after Radical Prostatectomy.** Vardenafil was studied in men following bilateral nerve-sparing radical prostatectomy.⁹
- **Raynaud's Phenomenon.** Vardenafil has been studied in patients with Raynaud's phenomenon.^{3,4} Vardenafil improved digital blood flow and decreased the number of Raynaud's attacks. Guidelines from the European League against Rheumatism (EULAR) on the treatment of systemic sclerosis (2023) recommend considering dihydropyridine calcium channel blockers (CCBs), usually oral nifedipine, for first-line therapy of Raynaud's phenomenon in patients with systemic sclerosis.¹⁰ Phosphodiesterase type 5 inhibitors should also be considered in such clinical scenarios.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of vardenafil tablets and vardenafil orally disintegrating tablets. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with vardenafil as well as the monitoring required for adverse events and long-term efficacy, some approvals require vardenafil to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: When available, the ICD-10 codes for male erectile dysfunction (ICD-10: N52.*) will be used for automation to allow approval of the requested medication. This automation is gender-selective and is not applicable for women; approval for use in women is always determined by Prior Authorization criteria.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of vardenafil is recommended in those who meet one of the following criteria:

11/06/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

FDA-Approved Indication

16. Erectile Dysfunction. Approve for 1 year.

Other Uses with Supportive Evidence

17. Benign Prostatic Hyperplasia. Approve for 1 year if the patient meets ONE of the following (A or B):

Note: For men with erectile dysfunction and benign prostatic hyperplasia, use criterion 1 above.

A) Patient has tried an alpha-1 (α 1) blocker; OR

Note: Examples of alpha-1 (α 1) blockers include doxazosin, terazosin, tamsulosin, and alfuzosin.

B) Patient has tried a 5 α -reductase inhibitor.

Note: Examples of 5 α -reductase inhibitor includes finasteride and dutasteride.

18. Prophylaxis After Radical Prostatectomy (Early Penile Rehabilitation). Approve for 1 year if the patient meets BOTH of the following (A and B):

A) Patient had a radical prostatectomy within the previous 12 months; AND

B) The medication is prescribed by or in consultation with a urologist.

19. Raynaud's Phenomenon. Approve for 1 year if the patient meets ONE of the following (A or B):

A) Patient has tried at least one calcium channel blocker; OR

Note: Examples of calcium channel blockers include amlodipine, felodipine, and nifedipine.

B) According to the prescriber, use of a calcium channel blocker is contraindicated.

Note: Examples of reasons a patient cannot take a calcium channel blocker include right heart failure and decreased cardiac output.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of vardenafil is not recommended in the following situations:

1. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Erythropoiesis-Stimulating Agents – Aranesp Prior Authorization Policy

- Aranesp® (darbepoetin alfa intravenous or subcutaneous injection – Amgen)

REVIEW DATE: 07/17/2024

OVERVIEW

Aranesp, an erythropoiesis-stimulating agent (ESA), is indicated for the following uses:¹

- **Anemia due to chronic kidney disease (CKD)**, including patients on dialysis and patients not on dialysis.
- **Anemia due to chemotherapy in patients with cancer**, in patients with non-myeloid malignancies where anemia is due to the effect of concomitant myelosuppressive chemotherapy, and upon initiation, there is a minimum of two additional months of planned chemotherapy.

Aranesp has not been shown to improve quality of life, fatigue, or patient well-being.¹ Aranesp is not indicated for the following uses:

- In patients with cancer receiving hormonal agents, biologic products, or radiotherapy unless also receiving concomitant myelosuppressive chemotherapy.
- In patients with cancer receiving myelosuppressive chemotherapy when the anticipated outcome is cure.
- In patients with cancer receiving myelosuppressive chemotherapy in whom anemia can be managed by transfusion.
- As a substitute for red blood cell (RBC) transfusions in those who require immediate correction of anemia.

The iron status should be evaluated in all patients before and during treatment.¹ Therapy should be initiated for **adults with CKD on dialysis** when the hemoglobin (Hb) level is < 10.0 g/dL and if the Hb level approaches or exceeds 11.0 g/dL, reduce or interrupt the Aranesp dose. For **adults with CKD who are not on dialysis**, consider initiating Aranesp only when Hb is < 10.0 g/dL and other considerations apply (e.g., rate of Hb decline indicates patient is likely to need RBC transfusion and reducing the risk of alloimmunization and/or other RBC transfusion-related risks is a goal). If the Hb level exceeds 10.0 g/dL, reduce or interrupt the Aranesp dose and use the lowest dose sufficient to reduce the need for RBC transfusions. For **pediatric patients with CKD**, initiate Aranesp when the Hb < 10.0 g/dL and if the Hb level approaches 12.0 g/dL, reduce or interrupt the dose of Aranesp. Initiate Aranesp for **patients on cancer chemotherapy** only if the Hb is < 10.0 g/dL and if there is a minimum of two additional months of planned chemotherapy. Use the lowest dose of Aranesp to avoid RBC transfusions.

Guidelines

The Kidney Disease Improving Global Outcomes (KDIGO) clinical practice guidelines for anemia in CKD (2012) state that for adults with CKD on dialysis, ESA therapy should be used to avoid having the Hb concentration fall below 9.0 g/dL by initiating ESA therapy when the Hb is between 9.0 and 10.0 g/dL.² The guidelines recommend against ESA therapy for adult patients with CKD who are not on dialysis when Hb levels are ≥ 10.0 g/dL. For adult patients with CKD who are not on dialysis with Hb levels < 10.0 g/dL, the decision whether to initiate ESA therapy should be individualized based on many factors (e.g., prior response to iron therapy, the risk of needing a transfusion, presence of symptoms). In general, ESAs should not be used to maintain Hb concentrations above 11.5 g/dL in adult patients with CKD. For pediatric patients with CKD, the Hb concentration in which ESAs should be initiated in the individual patient should

07/17/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

be considered while being aware of the potential benefits and potential harms. In all pediatric patients with CKD receiving ESA therapy, the selected Hb concentration should be in the range of 11.0 to 12.0 g/dL. Iron supplementation can improve response to ESA therapy. Baseline and periodic monitoring (e.g., iron, total iron-binding capacity, transferrin saturation, or ferritin levels) and instituting iron replacement when needed may be useful in limiting the need for ESAs, maximizing symptomatic improvement in patients, and determining the reason for inadequate response to ESAs. Iron deficiency can occur following continued ESA use. Therefore, iron supplementation is required in most patients to maintain an optimal response.

Aranesp is recommended in guidelines from the National Comprehensive Cancer Network (NCCN):

- **Myelodysplastic Syndrome (MDS):** NCCN guidelines (version 2.2024 – May 22, 2024) list Aranesp and epoetin alfa products as having utility in anemic, symptomatic patients with MDS if serum erythropoietin levels are ≤ 500 mU/mL.³ Iron stores should be adequate. Due to safety issues, the guidelines suggest that ESAs be used in the management of symptomatic anemia in patients with MDS and to aim for a target Hb range of 10 to 12.0 g/dL but not to exceed 12.0 g/dL.
- **Myeloproliferative Neoplasms:** The NCCN guidelines (version 1.2024 – December 21, 2023) address Aranesp and epoetin alfa products as options for treatment of patients with anemia related to myelofibrosis having a serum erythropoietin level < 500 mU/mL.⁴ Iron stores should be adequate. The guidelines also advise that ESAs are generally less effective for the management of transfusion-dependent anemia.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Aranesp in patients with conditions other than CKD who are on dialysis. The intent of this policy is to provide recommendations for uses other than anemia in patients with CKD who are on dialysis. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Aranesp as well as the monitoring required for adverse events and long-term efficacy, approval requires Aranesp to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Aranesp is recommended in those who meet one of the following criteria:

FDA-Approved Indications

1. **Anemia in a Patient with Chronic Kidney Disease who is on Dialysis.** Approve for 3 years.
2. **Anemia in a Patient with Chronic Kidney Disease who is not on Dialysis.** Approve for 1 year if the patient meets ONE of the following (A or B):
 - A) **Initial Therapy.** Approve if the patient meets BOTH of the following (i and ii):
 - i. Patient meets ONE of the following (a or b):
 - a) Patient is ≥ 18 years of age with a hemoglobin < 10.0 g/dL; OR
 - b) Patient is < 18 years of age with a hemoglobin ≤ 11.0 g/dL; AND
 - ii. Patient meets ONE of the following (a or b):
 - a) Patient is currently receiving iron therapy; OR
 - b) Patient has adequate iron stores according to the prescriber; OR

B) Patient is Currently Receiving an Erythropoiesis-Stimulating Agent. Approve if the patient meets BOTH of the following (i and ii):

Note: Examples of erythropoiesis-stimulating agents include an epoetin alfa product (e.g., Epogen, Procrit, or Retacrit), a darbepoetin alfa product (e.g., Aranesp), or a methoxy polyethylene glycol-epoetin beta product (e.g., Mircera).

- i. Patient has a hemoglobin ≤ 12.0 g/dL; AND
- ii. Patient meets ONE of the following (a or b):
 - a) Patient is currently receiving iron therapy; OR
 - b) Patient has adequate iron stores according to the prescriber.

3. Anemia in a Patient with Cancer due to Cancer Chemotherapy. Approve for 6 months if the patient meets ONE of the following (A or B):

A) Initial Therapy. Approve if the patient meets ALL of the following (i, ii, and iii):

- i. Patient has a hemoglobin < 10.0 g/dL; AND
- ii. Patient meets BOTH of the following (a and b):
 - a) Patient is currently receiving myelosuppressive chemotherapy; AND
 - b) According to the prescriber, myelosuppressive chemotherapy is considered non-curative; AND
- iii. Patient meets ONE of the following (a or b):
 - a) Patient is currently receiving iron therapy; OR
 - b) Patient has adequate iron stores according to the prescriber; OR

B) Patient is Currently Receiving an Erythropoiesis-Stimulating Agent. Approve if the patient meets ALL of the following (i, ii, and iii):

Note: Examples of erythropoiesis-stimulating agents include an epoetin alfa product (e.g., Epogen, Procrit, or Retacrit) or a darbepoetin alfa product (e.g., Aranesp).

- i. Patient has a hemoglobin ≤ 12.0 g/dL; AND
- ii. Patient meets BOTH of the following (a and b):
 - a) Patient is currently receiving myelosuppressive chemotherapy; AND
 - b) According to the prescriber, myelosuppressive chemotherapy is considered non-curative; AND
- iii. Patient meets ONE of the following (a or b):
 - a) Patient is currently receiving iron therapy; OR
 - b) Patient has adequate iron stores according to the prescriber.

Other Uses with Supportive Evidence

4. Anemia Associated with Myelodysplastic Syndrome. Approve for 1 year if the patient meets ONE of the following (A or B):

A) Initial Therapy. Approve if the patient meets ALL of the following (i, ii, iii, and iv):

- i. Patient is ≥ 18 years of age; AND
- ii. Patient meets ONE of the following (a or b):
 - a) Patient has a hemoglobin < 10.0 g/dL; OR
 - b) Patient has a serum erythropoietin level ≤ 500 mU/mL; AND
- iii. Patient meets ONE of the following (a or b):
 - a) Patient is currently receiving iron therapy; OR
 - b) Patient has adequate iron stores according to the prescriber; AND
- iv. The medication is prescribed by or in consultation with a hematologist or oncologist.

B) Patient is Currently Receiving an Erythropoiesis-Stimulating Agent. Approve if the patient meets ALL of the following (i, ii, iii, and iv):

Note: Examples of erythropoiesis-stimulating agents include an epoetin alfa product (e.g., Epogen, Procrit, or Retacrit) or a darbepoetin alfa product (e.g., Aranesp).

- i. Patient is ≥ 18 years of age; AND
 - ii. Patient has a hemoglobin ≤ 12.0 g/dL; AND
 - iii. Patient meets ONE of the following (a or b):
 - a) Patient is currently receiving iron therapy; OR
 - b) Patient has adequate iron stores according to the prescriber; AND
 - iv. The medication is prescribed by or in consultation with a hematologist or oncologist.
5. **Anemia Associated with Myelofibrosis.** Approve for the duration noted below if the patient meets the following (A or B):
- A) Initial Therapy. Approve for 3 months if the patient meets ALL of the following (i, ii, and iii):
- i. Patient meets ONE of the following (a or b):
 - a) Patient has a hemoglobin < 10.0 g/dL; OR
 - b) Patient has a serum erythropoietin level ≤ 500 mU/mL; AND
 - ii. Patient meets ONE of the following (a or b):
 - a) Patient is currently receiving iron therapy; OR
 - b) Patient has adequate iron stores according to the prescriber; AND
 - iii. The medication is prescribed by or in consultation with a hematologist or oncologist.
- B) Patient is Currently Receiving an Erythropoiesis-Stimulating Agent. Approve for 1 year if the patient meets ALL of the following (i, ii, iii, and iv):
- Note: Examples of erythropoiesis-stimulating agents include an epoetin alfa product (e.g., Epogen, Procrit, or Retacrit) or a darbepoetin alfa product (e.g., Aranesp).
- i. Patient has a hemoglobin ≤ 12.0 g/dL; AND
 - ii. Patient meets ONE of the following (a or b):
 - a) Patient is currently receiving iron therapy; OR
 - b) Patient has adequate iron stores according to the prescriber; AND
 - iii. According to the prescriber, patient has responded to therapy defined as hemoglobin ≥ 10 g/dL or a hemoglobin increase of ≥ 2 g/dL; AND
 - iv. The medication is prescribed by or in consultation with a hematologist or oncologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Aranesp is not recommended in the following situations:

1. **Anemia Associated with Cancer in a Patient not Receiving Myelosuppressive Cancer Chemotherapy.** Aranesp is not indicated in patients with cancer who are not receiving cancer chemotherapy.¹
2. **Anemia Associated with Acute Myelogenous Leukemias (AML), Chronic Myelogenous Leukemias (CML), or other Myeloid Cancers.** Aranesp is indicated for use in non-myeloid cancers. AML and CML are examples of myeloid cancers.¹
3. **Anemia Associated with Radiotherapy in Cancer.** Aranesp is not indicated for use in patients with cancer who are given only radiation therapy.¹
4. **To Enhance Athletic Performance.** Aranesp is not recommended for approval because this indication is excluded from coverage in a typical pharmacy benefit.
5. **Anemia due to Acute Blood Loss.** Use of Aranesp is not appropriate in these types of situations.

PRIOR AUTHORIZATION POLICY

POLICY: Erythropoiesis-Stimulating Agents – Epoetin Alfa Products Prior Authorization Policy

- Epogen® (epoetin alfa intravenous or subcutaneous injection – Amgen)
- Procrit® (epoetin alfa intravenous or subcutaneous injection – Janssen)
- Retacrit® (epoetin alfa-epbx intravenous or subcutaneous injection – Pfizer)

REVIEW DATE: 07/17/2024

OVERVIEW

Epoetin alfa (Epogen, Procrit, Retacrit), an erythropoiesis-stimulating agent (ESA), is indicated for the following uses:¹⁻³

- **Anemia due to chronic kidney disease (CKD)**, including patients on dialysis and patients not on dialysis to decrease the need for red blood cell (RBC) transfusions.
- **Anemia due to chemotherapy in patients with cancer**, in patients with non-myeloid malignancies where anemia is due to the effect of concomitant myelosuppressive chemotherapy, and upon initiation, there is a minimum of two additional months of planned chemotherapy.
- **Anemia due to zidovudine**, in patients with human immunodeficiency virus (HIV) infection.
- **Reduction of allogeneic RBC transfusions**, in patients with perioperative hemoglobin (Hb) > 10.0 to ≤ 13.0 g/dL who are at high risk for perioperative blood loss from elective, noncardiac, nonvascular surgery.

Retacrit is a biosimilar to Epogen/Procrit.³ Epoetin alfa has not been shown to improve quality of life, fatigue, or patient well-being.¹⁻³ Epoetin alfa is not indicated for the following uses:

- Patients with cancer receiving hormonal agents, biologic products, or radiotherapy unless also receiving concomitant myelosuppressive chemotherapy.
- Patients with cancer receiving myelosuppressive chemotherapy when the anticipated outcome is cure.
- Patients with cancer receiving myelosuppressive chemotherapy in whom anemia can be managed by transfusion.
- Patients scheduled for surgery who are willing to donate autologous blood.
- Patients undergoing cardiac or vascular surgery.
- As a substitute for RBC transfusions in those who require immediate correction of anemia.

The iron status should be evaluated in all patients before and during treatment with epoetin alfa.¹⁻³ Therapy should be initiated for **adults with CKD on dialysis** when the Hb level is < 10.0 g/dL and if the Hb level approaches or exceeds 11.0 g/dL, reduce or interrupt the dose of epoetin alfa. For **adults with CKD who are not on dialysis**, consider initiating epoetin alfa only when the Hb is < 10.0 g/dL and other considerations apply (e.g., rate of Hb decline indicates patient is likely to need RBC transfusion and reducing the risk of alloimmunization and/or other RBC transfusion-related risks is a goal). If the Hb exceeds 10.0 g/dL, reduce or interrupt the epoetin alfa dose and use the lowest dose sufficient to reduce the need for RBC transfusions. For **pediatric patients with CKD**, initiate epoetin alfa when the Hb < 10.0 g/dL and if the Hb level approaches 12.0 g/dL, reduce or interrupt the dose of epoetin alfa. Initiate epoetin alfa for **patients on cancer chemotherapy** only if the Hb is < 10.0 g/dL. Use the lowest dose of epoetin alfa necessary to avoid RBC transfusions. Epoetin alfa is indicated for the treatment of **anemia due to zidovudine** given at ≤ 4,200 mg per week in HIV-infected patients with endogenous serum erythropoietin levels of ≤ 500 mU/mL. It is recommended to withhold epoetin alfa if Hb exceeds 12.0 g/dL. Data show that epoetin alfa elevated or maintained Hb and/or hematocrit and decreased transfusions in anemic patients

07/17/2024

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

(Hb < 10.0 g/dL) who were receiving zidovudine. Patients with baseline endogenous serum erythropoietin levels $\leq$ 500 mU/mL derived greater benefit with epoetin alfa (e.g., achievement of higher hematocrit, reduction in transfusion requirements) compared with those having levels greater than this threshold.

Guidelines

The Kidney Disease Improving Global Outcomes (KDIGO) clinical practice guidelines for anemia in CKD (2012) state that for adults with CKD on dialysis ESA therapy should be used to avoid having the Hb concentration fall below 9.0 g/dL by initiating ESA therapy when the Hb is between 9.0 and 10.0 g/dL.⁴ The guidelines recommend against ESA therapy for adult patients with CKD who are not on dialysis when Hb levels are $\geq$ 10.0 g/dL. For adult patients with CKD who are not on dialysis with Hb levels < 10.0 g/dL, the decision whether to initiate ESA therapy should be individualized based on many factors (e.g., prior response to iron therapy, the risk of needing a transfusion, presence of symptoms). In general, ESAs should not be used to maintain Hb concentrations above 11.5 g/dL in adult patients with CKD. For pediatric patients with CKD, the Hb concentration in which ESAs should be initiated in the individual patient should be considered while being aware of the potential benefits and potential harms. In all pediatric patients with CKD receiving ESA therapy, the selected Hb concentration should be in the range of 11.0 to 12.0 g/dL. Iron supplementation can improve response to ESA therapy. Baseline and periodic monitoring (e.g., iron, total iron-binding capacity, transferrin saturation, or ferritin levels) and instituting iron replacement when needed may be useful in limiting the need for ESAs, maximizing symptomatic improvement in patients, and determining the reason for inadequate response to ESAs. Iron deficiency can occur following continued ESA use. Therefore, iron supplementation is required in most patients to maintain an optimal response.

Epoetin alfa is recommended in guidelines from the National Comprehensive Cancer Network (NCCN):

- **Myelodysplastic Syndrome (MDS):** NCCN guidelines (version 2.2024 – May 22, 2024) list Aranesp and epoetin alfa products as having utility in anemic, symptomatic patients with MDS if serum erythropoietin levels are $\leq$ 500 mU/mL.⁵ Iron stores should be adequate. Due to safety issues, the guidelines suggest that ESAs be used in the management of symptomatic anemia in patients with MDS and to aim for a target Hb range of 10 to 12.0 g/dL but not to exceed 12.0 g/dL.
- **Myeloproliferative Neoplasms:** The NCCN guidelines (version 1.2024 – December 21, 2023) address Aranesp and epoetin alfa products as options for treatment of patients with anemia related to myelofibrosis having a serum erythropoietin level < 500 mU/mL.⁶ Iron stores should be adequate. The guidelines also advise that ESAs are generally less effective for the management of transfusion-dependent anemia.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of epoetin alfa products in patients with conditions other than CKD who are on dialysis. The intent of this policy is to provide recommendations for uses other than anemia in patients with CKD who are on dialysis. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with epoetin alfa as well as the monitoring required for adverse events and long-term efficacy, approval requires epoetin alfa to be prescribed by or in consultation with a physician who specializes in the condition being treated in some circumstances.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of epoetin alfa is recommended in those who meet one of the following criteria:

07/17/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

FDA-Approved Indications

4. **Anemia in a Patient with Chronic Kidney Disease who is on Dialysis.** Approve for 3 years.
5. **Anemia in a Patient with Chronic Kidney Disease who is not on Dialysis.** Approve for 1 year if the patient meets ONE of the following (A or B):
 - C) Initial Therapy. Approve if the patient meets BOTH of the following (i and ii):
 - iii. Patient meets ONE of the following (a or b):
 - c) Patient is ≥ 18 years of age with a hemoglobin < 10.0 g/dL; OR
 - d) Patient is < 18 years of age with a hemoglobin ≤ 11.0 g/dL; AND
 - iv. Patient meets ONE of the following (a or b):
 - c) Patient is currently receiving iron therapy; OR
 - d) Patient has adequate iron stores according to the prescriber; OR
 - D) Patient is Currently Receiving an Erythropoiesis-Stimulating Agent. Approve if the patient meets BOTH of the following (i and ii):

Note: Examples of erythropoiesis-stimulating agents include an epoetin alfa product (e.g., Epogen, Procrit, or Retacrit), a darbepoetin alfa product (e.g., Aranesp), or a methoxy polyethylene glycol-epoetin beta product (e.g., Mircera).

 - iii. Patient has a hemoglobin ≤ 12.0 g/dL; AND
 - iv. Patient meets ONE of the following (a or b):
 - c) Patient is currently receiving iron therapy; OR
 - d) Patient has adequate iron stores according to the prescriber.
6. **Anemia in a Patient with Cancer due to Cancer Chemotherapy.** Approve for 6 months if the patient meets ONE of the following (A or B):
 - C) Initial Therapy. Approve if the patient meets ALL the following (i, ii, and iii):
 - iv. Patient has a hemoglobin < 10.0 g/dL; AND
 - v. Patient meets BOTH of the following (a and b):
 - a) Patient is currently receiving myelosuppressive chemotherapy; AND
 - b) According to the prescriber, myelosuppressive chemotherapy is considered non-curative; AND
 - vi. Patient meets ONE of the following (a or b):
 - c) Patient is currently receiving iron therapy; OR
 - d) Patient has adequate iron stores according to the prescriber; OR
 - D) Patient is Currently Receiving an Erythropoiesis-Stimulating Agent. Approve if the patient meets ALL of the following (i, ii, and iii):

Note: Examples of erythropoiesis-stimulating agents include an epoetin alfa product (e.g., Epogen, Procrit, or Retacrit) or a darbepoetin alfa product (e.g., Aranesp).

 - iv. Patient has a hemoglobin ≤ 12.0 g/dL; AND
 - v. Patient meets BOTH of the following (a and b):
 - c) Patient is currently receiving myelosuppressive chemotherapy; AND
 - d) According to the prescriber, myelosuppressive chemotherapy is considered non-curative; AND
 - vi. Patient meets ONE of the following (a or b):
 - c) Patient is currently receiving iron therapy; OR
 - d) Patient has adequate iron stores according to the prescriber.
4. **Anemia in a Patient with Human Immunodeficiency Virus who is Receiving Zidovudine.** Approve for 1 year if the patient meets ONE of the following (A or B):
 - A) Initial Therapy. Approve if the patient meets ALL of the following (i, ii, and iii):

- i. Patient meets ONE of the following (a or b):
 - a) Patient has a hemoglobin < 10.0 g/dL; OR
 - b) Patient has a serum erythropoietin level $\leq$ 500 mU/mL; AND
 - ii. Patient is currently receiving zidovudine therapy; AND
 - iii. Patient meets ONE of the following (a or b):
 - a) Patient is currently receiving iron therapy; OR
 - b) Patient has adequate iron stores according to the prescriber; OR
 - B) Patient is Currently Receiving an Erythropoiesis-Stimulating Agent.** Approve if the patient meets ALL of the following (i, ii, and iii):
Note: Examples of erythropoiesis-stimulating agents include an epoetin alfa product (e.g., Epogen, Procrit, or Retacrit) or darbepoetin alfa product (e.g., Aranesp).
 - iv. Patient has a hemoglobin $\leq$ 12.0 g/dL; AND
 - v. Patient is currently receiving zidovudine therapy; AND
 - vi. Patient meets ONE of the following (a or b):
 - a) Patient is currently receiving iron therapy; OR
 - b) Patient has adequate iron stores according to the prescriber.
- 5. Reduction of Allogeneic Red Blood Cell Transfusions in a Patient Undergoing Surgery.** Approve for 1 month if the patient meets ALL of the following (A, B, C, and D):
- A) Hemoglobin is $\leq$ 13.0 g/dL; AND
 - B) The surgery is elective, nonvascular, and noncardiac; AND
 - C) Patient is not willing or able to donate autologous blood prior to surgery; AND
 - D) Patient meets ONE of the following (i or ii):
 - i. Patient is currently receiving iron therapy; OR
 - ii. Patient has adequate iron stores according to the prescriber.

Other Uses with Supportive Evidence

- 6. Anemia Associated with Myelodysplastic Syndrome.** Approve for 1 year if the patient meets ONE of the following (A or B):
- C) Initial Therapy. Approve if the patient meets ALL of the following (i, ii, iii, and iv):
 - iv. Patient is $\geq$ 18 years of age; AND
 - v. Patient meets ONE of the following (a or b):
 - a) Patient has a hemoglobin < 10.0 g/dL; OR
 - b) Patient has a serum erythropoietin level $\leq$ 500 mU/mL; AND
 - vi. Patient meets ONE of the following (a or b):
 - c) Patient is currently receiving iron therapy; OR
 - d) Patient has adequate iron stores according to the prescriber; AND
 - iv. The medication is prescribed by or in consultation with a hematologist or oncologist.
 - B) Patient is Currently Receiving an Erythropoiesis-Stimulating Agent.** Approve if the patient meets ALL of the following (i, ii, iii, and iv):
Note: Examples of erythropoiesis-stimulating agents include an epoetin alfa product (e.g., Epogen, Procrit, or Retacrit) or a darbepoetin alfa product (e.g., Aranesp).
 - i. Patient is $\geq$ 18 years of age; AND
 - ii. Patient has a hemoglobin $\leq$ 12.0 g/dL; AND
 - iii. Patient meets ONE of the following (a or b):
 - c) Patient is currently receiving iron therapy; OR
 - d) Patient has adequate iron stores according to the prescriber; AND
 - iv. The medication is prescribed by or in consultation with a hematologist or oncologist.

7. **Anemia Associated with Myelofibrosis.** Approve for the duration noted below if the patient meets ONE of the following (A or B):
- A) Initial Therapy. Approve for 3 months if the patient meets ALL of the following (i, ii, and iii):
- i. Patient meets ONE of the following (a or b):
 - a) Patient has a hemoglobin < 10.0 g/dL; OR
 - b) Patient has a serum erythropoietin level $\leq$ 500 mU/mL; AND
 - ii. Patient meets ONE of the following (a or b):
 - a) Patient is currently receiving iron therapy; OR
 - b) Patient has adequate iron stores according to the prescriber; AND
 - iii. The medication is prescribed by or in consultation with a hematologist or oncologist.
- B) Patient is Currently Receiving an Erythropoiesis-Stimulating Agent. Approve for 1 year if the patient meets ALL of the following (i, ii, iii, and iv):
- Note: Examples of erythropoiesis-stimulating agents include an epoetin alfa product (e.g., Epogen, Procrit, or Retacrit) or a darbepoetin alfa product (e.g., Aranesp).
- i. Patient has a hemoglobin $\leq$ 12.0 g/dL; AND
 - ii. Patient meets ONE of the following (a or b):
 - a) Patient is currently receiving iron therapy; OR
 - b) Patient has adequate iron stores according to the prescriber; AND
 - iii. According to the prescriber, patient has responded to therapy defined as hemoglobin $\geq$ 10 g/dL or a hemoglobin increase of $\geq$ 2 g/dL; AND
 - iv. The medication is prescribed by or in consultation with a hematologist or oncologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Epoetin alfa is not recommended in the following situations:

7. **Anemia Associated with Cancer in a Patient not Receiving Myelosuppressive Cancer Chemotherapy.** Epoetin alfa is not indicated in patients with cancer who are not receiving cancer chemotherapy.¹⁻³
8. **Anemia Associated with Acute Myelogenous Leukemias (AML), Chronic Myelogenous Leukemias (CML), or other Myeloid Cancers.** Epoetin alfa is indicated for use in non-myeloid cancers. AML and CML are examples of myeloid cancers.¹⁻³
9. **Anemia Associated with Radiotherapy in Cancer.** Epoetin alfa is not indicated for use in patients with cancer who are given only radiation therapy.¹⁻³
10. **To Enhance Athletic Performance.** Epoetin alfa is not recommended for approval because this indication is excluded from coverage in a typical pharmacy benefit.
11. **Anemia due to Acute Blood Loss.** Use of epoetin alfa is not appropriate in these types of situations.
12. **Non-Anemic Patients (Hemoglobin > 13.0 g/dL) Prior to Surgery.** Although studies have been done that involved non-anemic patients undergoing various surgeries receiving epoetin alfa preoperatively and sometimes postoperatively to prevent transfusions or subsequent anemia, the overall benefit of this therapy in those with relatively normal preoperative Hb level is questionable.
13. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Erythropoiesis-Stimulating Agents – Mircera Prior Authorization Policy

- Mircera® (methoxy polyethylene glycol-epoetin beta intravenous or subcutaneous injection – Vifor)

REVIEW DATE: 06/12/2024

OVERVIEW

Mircera, an erythropoiesis-stimulating agent (ESA), is indicated for the treatment of **anemia due to chronic kidney disease (CKD)** including:¹

- Adults on dialysis and adults not on dialysis.
- Pediatric patients 3 months to 17 years of age on dialysis or not on dialysis who are converting from another ESA after their hemoglobin (Hb) level was stabilized with an ESA.

Mircera has not been shown to improve symptoms, physical functioning, or health-related quality of life.¹ Mircera is not indicated for the following uses:

- Treatment of anemia due to cancer chemotherapy.
- As a substitute for red blood cell (RBC) transfusions in those who require immediate correction of anemia.

Therapy should be initiated for adults with CKD on dialysis when the Hb level is < 10.0 g/dL. If the Hb level approaches or exceeds 11.0 g/dL, reduce or interrupt the dose of Mircera.¹ For adults with CKD not on dialysis, consider initiating Mircera only when the Hb is < 10.0 g/dL and other considerations apply (e.g., rate of Hb decline indicates patient is likely to need RBC transfusion and reducing the risk of alloimmunization and/or other RBC transfusion-related risks is a goal). If the Hb exceeds 10.0 g/dL, reduce or interrupt the Mircera dose and use the lowest dose sufficient to reduce the need for RBC transfusions. Therapy with Mircera for pediatric CKD patients should only be initiated when the Hb level has already been stabilized by treatment with an ESA (conversion therapy). If the Hb level approaches or exceeds 12.0 g/dL, reduce or interrupt the dose of Mircera.

Guidelines

The Kidney Disease Improving Global Outcomes (KDIGO) clinical practice guidelines for anemia in CKD (2012) state that for adults with CKD on dialysis ESA therapy should be used to avoid having the Hb concentration fall below 9.0 g/dL by initiating ESA therapy when the Hb is between 9.0 and 10.0 g/dL.² The guidelines recommend against ESA therapy for adult patients with CKD who are not on dialysis when Hb levels are ≥ 10.0 g/dL. For adult patients with CKD who are not on dialysis with Hb levels < 10.0 g/dL, the decision whether to initiate ESA therapy should be individualized based on many factors (e.g., prior response to iron therapy, the risk of needing a transfusion, presence of symptoms). In general, ESAs should not be used to maintain Hb concentrations above 11.5 g/dL in adult patients with CKD. For pediatric patients with CKD, the Hb concentration in which ESAs should be initiated in the individual patient should be considered while being aware of the potential benefits and potential harms. In all pediatric patients with CKD receiving ESA therapy, the selected Hb concentration should be in the range of 11.0 to 12.0 g/dL. Iron supplementation can improve response to ESA therapy. Baseline and periodic monitoring (e.g., iron, total iron-binding capacity, transferrin saturation, or ferritin levels) and instituting iron replacement when needed may be useful in limiting the need for ESAs, maximizing symptomatic improvement in patients, and determining the reason for inadequate response to ESAs. Iron deficiency can occur following continued ESA use. Therefore, iron supplementation is required in most patients to maintain an optimal response.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Mircera in patients with conditions other than CKD who are on dialysis. The intent of this policy is to provide recommendations for uses other than anemia in patients with CKD who are on dialysis. All approvals are provided for the duration noted below.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Mircera is recommended in those who meet the following:

FDA-Approved Indications

7. **Anemia in a Patient with Chronic Kidney Disease who is on Dialysis.** Approve for 3 years.
8. **Anemia in a Patient with Chronic Kidney Disease who is not on Dialysis.** Approve for 1 year if the patient meets ONE of the following (A or B):
 - A) **Initial Therapy.** Approve if the patient meets ALL of the following (i, ii, and iii):
 - i. Patient is ≥ 18 years of age; AND
 - ii. Patient has a hemoglobin < 10.0 g/dL; AND
 - iii. Patient meets ONE of the following (a or b):
 - a) Patient is currently receiving iron therapy; OR
 - b) Patient has adequate iron stores according to the prescriber; OR
 - B) **Patient is Currently Receiving an Erythropoiesis-Stimulating Agent.** Approve if the patient meets ALL of the following (i, ii, and iii):

Note: Examples of erythropoiesis-stimulating agents include an epoetin alfa product (e.g., Epogen, Procrit, or Retacrit), a darbepoetin alfa product (e.g., Aranesp), or a methoxy polyethylene glycol-epoetin beta product (e.g., Mircera).

 - i. If the patient is < 18 years of age, according to the prescriber, the hemoglobin level has been stabilized by treatment with an erythropoiesis-stimulating agent; AND

Note: Examples of erythropoiesis-stimulating agents include an epoetin alfa product (e.g., Epogen, Procrit, or Retacrit), a darbepoetin alfa product (e.g., Aranesp), or a methoxy polyethylene glycol-epoetin beta product (e.g., Mircera).
 - ii. Patient has a hemoglobin ≤ 12.0 g/dL; AND
 - iii. Patient meets ONE of the following (a or b):
 - a) Patient is currently receiving iron therapy; OR
 - b) Patient has adequate iron stores according to the prescriber.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Mircera is not recommended in the following situations:

14. **Anemia Associated with Cancer in a Patient Receiving Myelosuppressive Cancer Chemotherapy.** Mircera is not indicated and not recommended for the treatment of anemia due to cancer chemotherapy.¹

- 15. To Enhance Athletic Performance.** Mircera is not recommended for approval because this indication is excluded from coverage in a typical pharmacy benefit.
- 16. Anemia due to Acute Blood Loss.** Use of Mircera is not appropriate in these types of situations.
- 17.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Fabry Disease – Galafold Prior Authorization Policy

- Galafold® (migalastat capsules – Amicus Therapeutics)

REVIEW DATE: 11/06/2024

OVERVIEW

Galafold, an oral alpha-galactosidase A (α -Gal) pharmacological chaperone, is indicated for the treatment of **Fabry disease in adults with** an amenable galactosidase alpha gene (*GLA*) variant based on in vitro assay data.¹

Disease Overview

Fabry disease is a rare inherited X-linked lysosomal storage disorder.²⁻⁴ Absent or significantly reduced α -Gal activity leads to the accumulation of globotriaosylceramide (GL-3) in a wide variety of cells throughout the body. The accumulation of GL-3 leads to progressive multisystem disease, primarily impacting the kidney, heart, and nervous system.^{3,4} Life expectancy in patients with Fabry disease is reduced; median survival is typically 50 to 55 years in men and 70 years in women.²

Currently, there have been more than 800 mutations to the gene encoding α -Gal identified.⁵ About 60% are missense mutations resulting in single amino acid substitutions. Some of these mutated enzymes have activity levels similar to normal α -Gal; however, they have been found to be unstable and are retained in the endoplasmic reticulum.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Galafold. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Galafold as well as the monitoring required for adverse events and long-term efficacy, approval requires Galafold to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Galafold is recommended in those who meet the following criteria:

FDA-Approved Indication

- 39. Fabry Disease.** Approve for 1 year if the patient meets ALL of the following (A, B, and C):
- 14.** Patient is ≥ 18 years of age; AND
 - 15.** Patient has an amenable galactosidase alpha gene (*GLA*) variant based on in vitro assay data; AND
 - 16.** The medication is prescribed by or in consultation with a geneticist, nephrologist, or a physician who specializes in the treatment of Fabry disease.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

11/06/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Coverage of Galafold is not recommended in the following situations:

- 11. Concurrent Use with Fabrazyme (agalsidase beta intravenous infusion).** One small study (n = 23) assessed a single dose of Galafold (150 mg or 450 mg) used concurrently with Fabrazyme or agalsidase alpha. While a single dose of Galafold significantly increased α -Gal activity, the long-term safety and efficacy of concurrent use of Galafold and Fabrazyme has not been established.⁶ Galafold is not FDA approved for concurrent use with Fabrazyme.
- 12. Concurrent Use with Elfabrio (pegunigalsidase alfa intravenous infusion).** Galafold has not been evaluated for use in combination with Elfabrio. It is not FDA approved for concurrent use with enzyme replacement therapy.
- 13.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Familial Chylomicronemia Syndrome – Tryngolza Prior Authorization Policy

- Tryngolza™ (olezarsen subcutaneous injection – Ionis)

REVIEW DATE: 12/23/2024

OVERVIEW

Tryngolza, an apolipoprotein C-III (*APO-III*)-directed antisense oligonucleotide, is indicated as an adjunct to diet to reduce triglycerides in adults with familial chylomicronemia syndrome (FCS).¹ It is recommended to maintain a low-fat diet (≤ 20 grams of fat per day) in conjunction with Tryngolza.

Disease Overview

FCS is an ultrarare, genetic form of severe hypertriglyceridemia that impacts 1 to 10 per 1,000,000 persons in the US. Patients with FCS may have triglyceride levels in the thousands. Of note, normal triglyceride levels are < 150 mg/dL with levels above 500 mg/dL categorized as severe hypertriglyceridemia. In general, patients with FCS do not have adequate responses to triglyceride-lowering therapies (e.g., fibrates, omega-3 fatty acids). The high triglyceride levels lead to symptoms such as severe abdominal pain, inflammation of the pancreas (acute pancreatitis), and fatty deposits in the skin. Lipemia retinalis may occur, a condition in which the retinal veins of the eyes appear milky. Patients may develop symptoms of FCS in infancy but may not have the disease be known until adulthood. FCS is caused by biallelic pathogenic variants in five known genes (i.e., lipoprotein lipase [*LPL*], glycosylphosphatidylinositol-anchored high-density lipoprotein [HDL]-binding protein 1 [*GPIHBP1*], apolipoprotein A-V [*APOA5*], apolipoprotein C-II [*APOC2*], or lipase maturation factor 1 [*LMF1*]).

Clinical Efficacy

The efficacy of Tryngolza was evaluated in a randomized, placebo-controlled, double-blind, Phase III trial in patients with genetically identified FCS.^{1,2} A fasting triglyceride level ≥ 880 mg/dL was required. At study entry, patients who received the FDA-approved dose of Tryngolza ($n = 22$) had baseline mean triglyceride levels of 2,613 mg/dL; the value for this parameter in patients who received placebo ($n = 23$) was 2,585 mg/dL. Background medications were statins (27%), omega-3 fatty acids (42%), fibrates (49%), or other lipid-lowering therapies (13%). The difference between Tryngolza 80 mg and placebo in the percent change in fasting triglycerides from baseline to Month 6 was -42.5%.

Guidelines

Guidelines do not address Tryngolza. There are recommendations regarding the diagnosis and/or identification of FCS.^{3,4} An expert panel (2018) states the FCS is characterized by very high plasma triglyceride concentrations (> 885 mg/dL) in the untreated state.³ Patients with FCS experience physical complications including incapacitating abdominal pain, and severe recurrent acute pancreatitis. Other clinical symptoms include eruptive xanthomas, lipemia retinalis, and lower body weight. Neurologic symptoms may be present (e.g., irritability, memory problems, dementia). Pathogenic variants are also present in FCS-genes (i.e., *LPL*, *GPIHBP1*, *APOA5*, *APOC2*, or *LMF1*). An FSC score ≥ 10 is a strong predictor of the condition.³ Also, patients with a North America Familial Chylomicronemia Syndrome (NAFCS) score ≥ 45 are very likely to have classical FCS.

12/23/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Tryngolza. Because of the specialized skills required for evaluation and diagnosis of patients treated with Tryngolza as well as the monitoring required for adverse events and long-term efficacy, initial approval requires Tryngolza to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Documentation: Documentation is required for use of Tryngolza as noted in the criteria as **[documentation required]**. Documentation may include, but is not limited to, chart notes, laboratory tests, medical test results, claims records, prescription receipts, and/or other information.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Tryngolza is recommended in those who meet the following criteria:

FDA-Approved Indication

33. Familial Chylomicronemia Syndrome. Approve for 1 year if the patient meets ALL of the following (A, B, C, D, and E):

- A) Patient is ≥ 18 years of age; AND
- B) Patient has a fasting triglyceride level ≥ 880 mg/dL **[documentation required]**; AND
- C) The patient has undergone genetic testing and meets ONE of the following (i or ii):
 - i. Molecular genetic test results demonstrate biallelic pathogenic variants in at least one gene causing familial chylomicronemia syndrome **[documentation required]**; OR
Note: Examples of genes causing Familial Chylomicronemia Syndrome include lipoprotein lipase (*LPL*), glycosylphosphatidylinositol-anchored high-density lipoprotein-binding protein 1 (*GPIHBP1*), apolipoprotein A-V (*APOA5*), apolipoprotein C-II (*APOC2*), or lipase maturation factor 1 (*LMF1*).
 - ii. Molecular genetic test results are inconclusive and the patient has ONE of the following (a, b, c, d, or e) **[documentation required]**:
 - a) Patient has a familial chylomicronemia syndrome score ≥ 10 ; OR
 - b) Patient has a North American familial chylomicronemia syndrome score ≥ 45 ; OR
 - c) Patient has a history of pancreatitis; OR
 - d) Patient has a history of eruptive xanthomas; OR
 - e) Patient has a of lipemia retinalis; AND
- D) The medication will be used concomitantly with a low-fat diet; AND
- E) Medication is prescribed by a cardiologist, an endocrinologist, or a physician who focuses in the treatment of disorders related to severe hypertriglyceridemia.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Tryngolza is not recommended in the following situations:

89. Hypertriglyceridemia (in the absence of a confirmed diagnosis of familial chylomicronemia syndrome). A trial evaluated Tryngolza in patients with either moderate hypertriglyceridemia and elevated cardiovascular risk or with severe hypertriglyceridemia.⁵ However, Tryngolza is not FDA-approved for this use.¹

90. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

Appendix A. Familial Chylomicronemia Syndrome Score Diagnostic Criteria (for Patients with Fasting TGs > 885 mg/dL).^{3*}

TG(s) – Triglyceride(s); * The FCS score is the sum of all items cited above and a score ≥ 10 suggests that FCS is very likely.

Appendix B. North American Familial Chylomicronemia Syndrome Score Diagnostic Criteria.^{4†}

[†] This tool can be used to assist in the diagnosis of familial chylomicronemia syndrome. It should be utilized in patients ≥ 1 year of age with triglyceride (TG) levels ≥ 440 mg/dL. It may be useful in patients who have not been yet tested genetically for FCS, or in whom genetic testing was inconclusive. If patients ≥ 10 years of age, the tool should only be used for patients who are not responsive to fibrates and high-dose omega-3 fatty acids even when the patient is compliance with therapy; HIV – Human immunodeficiency virus; * A more comprehensive list of secondary factors are available; TG – Triglyceride; TC – Total cholesterol; ApoB – Apolipoprotein B.

PRIOR AUTHORIZATION POLICY

POLICY: Gamifant Prior Authorization Policy

- Gamifant® (emapalumab-lzsg intravenous infusion – Sobi)

REVIEW DATE: 01/08/2025

OVERVIEW

Gamifant, an anti-interferon gamma (IFN- γ) antibody, is indicated for the treatment of **primary hemophagocytic lymphohistiocytosis (HLH)** in adult and pediatric patients with refractory, recurrent, or progressive disease or intolerance with conventional HLH therapy.¹

Disease Overview

HLH is a syndrome characterized by signs and symptoms of extreme inflammation, caused by defects in cytotoxic function (cytotoxic T cells and natural killer cells).² The incidence is estimated at 1.2 cases per million individuals per year, but this is likely an underestimate.³ In healthy individuals, cytotoxic function is important to terminate immune responses when appropriate by targeting and destroying activated immune cells. Deficiencies in cytotoxic function lead to an unchecked immune response and hyper-inflammation. Primary HLH has a clear genetic cause, whereas secondary HLH is triggered by a concomitant infection or medical condition, such as Epstein-Barr virus infection, malignancy, or rheumatologic disorders. IFN- γ normally has both pro-inflammatory functions (e.g., macrophage activation) and anti-inflammatory functions (e.g., activation of cytotoxic cells).^{4,5} However, in HLH, the anti-inflammatory action of IFN- γ is ineffective due to impaired cytotoxic cell activity; thus, pro-inflammatory effects predominate.

Guidelines

The HLH-2004 treatment protocol, developed by the Histiocyte Society, is the current standard of care for diagnostic and therapeutic guidelines.⁶ Gamifant is not addressed in the 2004 protocol. To establish a diagnosis of HLH, patients must either have a molecular diagnosis consistent with HLH or meet five out of eight diagnostic criteria. A backbone of etoposide and systemic dexamethasone is the conventional standard of care to induce symptomatic resolution; cyclosporine A and anti-thymocyte globulin have also demonstrated efficacy. Although chemotherapy prolongs survival in primary HLH, a hematopoietic stem cell transplant (HSCT) is needed for cure. Patients with primary HLH should continue chemotherapy (usually with etoposide, cyclosporine A, and dexamethasone) until HSCT can be performed. Myelotoxicity due to chemotherapy is a concern, especially since patients with HLH can have severe cytopenias and immunodeficiency at baseline.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Gamifant. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Gamifant, approval requires it to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

01/08/2025

© 2025. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Coverage of Gamifant is recommended for those who meet the following criteria:

FDA-Approved Indication

- 4. Hemophagocytic Lymphohistiocytosis, Primary.** Approve Gamifant for 6 months if the patient meets ALL of the following (A, B, C, and D):
- A)** Patient has a diagnosis of hemophagocytic lymphohistiocytosis determined by at least ONE of the following (i or ii):
- i.** Patient has a molecular genetic diagnosis consistent with hemophagocytic lymphohistiocytosis; OR
 - ii.** Prior to treatment, the patient meets at least FIVE of the following diagnostic criteria at baseline (FIVE of a, b, c, d, e, f, g, or h):
 - a)** Fever $\geq 38.5^{\circ}\text{C}$; OR
 - b)** Splenomegaly; OR
 - c)** Cytopenias defined as at least TWO of the following (TWO of 1, 2, or 3):
 - 1)** Hemoglobin $< 9\text{ g/dL}$ (or $< 10\text{ g/dL}$ in infants less than 4 weeks of age);
 - 2)** Platelets $< 100 \times 10^9/\text{L}$; OR
 - 3)** Neutrophils $< 1.0 \times 10^9/\text{L}$; OR
 - d)** Patient meets ONE of the following (1 or 2):
 - 1)** Fasting triglycerides $\geq 265\text{ mg/dL}$; OR
 - 2)** Fibrinogen $\leq 1.5\text{ g/L}$; OR
 - e)** Hemophagocytosis in bone marrow, spleen, or lymph nodes; OR
 - f)** Low or absent natural killer cell activity (according to local laboratory reference); OR
 - g)** Ferritin $\geq 500\text{ mcg/L}$; OR
 - h)** Soluble CD25 (i.e., soluble interleukin-2 receptor) $\geq 2,400\text{ U/mL}$; AND
- B)** Patient has tried at least one conventional therapy (e.g., etoposide, cyclosporine A, or anti-thymocyte globulin); AND
- C)** According to the prescriber, the patient has experienced at least ONE of the following (i or ii):
- i.** Refractory, recurrent, or progressive disease during conventional therapy (e.g., etoposide, cyclosporine A, or anti-thymocyte globulin); OR
 - ii.** Intolerance to conventional therapy (e.g., etoposide, cyclosporine A, or anti-thymocyte globulin); AND
- D)** The medication is prescribed by or in consultation with a hematologist, oncologist, immunologist, transplant specialist, or physician who specializes in hemophagocytic lymphohistiocytosis or related disorders.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Gamifant is not recommended in the following situations:

- 6.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Gastroenterology – Eohilia Prior Authorization Policy

- Eohilia™ (budesonide oral suspension – Takeda)

REVIEW DATE: 03/06/2024

OVERVIEW

Eohilia, a corticosteroid, is indicated for the treatment of **eosinophilic esophagitis (EoE) for 12 weeks in adults and pediatric patients ≥ 11 years of age**.¹ Use of Eohilia has not been shown to be safe and effective for the treatment of EoE for longer than 12 weeks.

Clinical Efficacy

In two pivotal trials of Eohilia, patients were required to have histologic evidence of EoE, defined as ≥ 15 eosinophils per high-power field despite 6 to 8 weeks of treatment with a high-dose proton pump inhibitor.^{2,3} Patients in both trials received 12 weeks of therapy with Eohilia. There are no data to address the time frame at which another 12-week course of Eohilia would be appropriate in patients who initially respond to treatment, but relapse following discontinuation. However, an extension study enrolled patients who were considered to be full responders to Eohilia in an initial 12-week trial and subsequently re-randomized them to either continue Eohilia or switch to placebo.⁴ Patients who were switched to placebo and then relapsed could reinitiate blinded Eohilia treatment at the next study visit. Over the 36-week extension, seven patients receiving placebo relapsed and reinitiated Eohilia therapy. Of these seven, one patient was an outlier and reinitiated therapy at Week 8 due to an unscheduled endoscopy. The remaining patients relapsed and reinitiated therapy with Eohilia between 4 and 7 months following the initial discontinuation of Eohilia therapy.

Guidelines

Guidelines for the management of EoE from the American Gastroenterological Association and the Joint Task Force on Allergy-Immunology Practice Parameters (2020) have not been updated since the FDA approval of Dupixent® (dupilumab subcutaneous injection) for this indication.⁵ In patients with symptomatic disease, use of a proton pump inhibitor is recommended over no treatment, as is treatment with topical swallowed corticosteroids (formulations not specified). Guidelines recommend diet modifications, such as an elemental diet (amino-acid based formulas) or an elimination diet, over no treatment. However, it is noted that patients who put a higher value on avoiding the challenges of adherence to these diets and the prolonged process of dietary reintroduction may reasonably decline this treatment option.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Eohilia. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Eohilia as well as the monitoring required for adverse events and long-term efficacy, approval requires Eohilia to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

03/06/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Coverage of Eohilia is recommended in those who meet the following criteria:

FDA-Approved Indication

- 1. Eosinophilic Esophagitis.** Approve for 12 weeks, if the patient meets the following (A, B, C, D, E and F):
 - A)** Patient is ≥ 11 years of age; AND
 - B)** Patient has a diagnosis of eosinophilic esophagitis as confirmed by an endoscopic biopsy demonstrating ≥ 15 intraepithelial eosinophils per high-power field; AND
 - C)** Patient meets ONE of the following (i or ii):
 - i.** Patient has received at least 8 weeks of therapy with a proton pump inhibitor; OR
Note: Treatment with a proton pump inhibitor currently or at any time in the past would count toward this requirement.
 - ii.** According to the prescriber, the patient has severe disease with esophageal stricture; AND
 - D)** Patient meets ONE of the following (i or ii):
 - i.** Patient has tried dietary modifications to manage eosinophilic esophagitis; OR
 - ii.** The prescriber has determined that the patient is not an appropriate candidate for dietary modifications; AND
Note: Examples of dietary modifications to treat eosinophilic esophagitis include an elemental diet or an elimination diet.
 - E)** Patients meets ONE of the following (i or ii):
 - i.** Patient is currently receiving a course of Eohilia and additional medication is needed to complete a 12-week course of treatment; OR
Note: The maximum recommended treatment is for 12 weeks. For a patient who has started therapy but has not completed 12 weeks, approve the remaining number of weeks for the patient to receive a total of 12 weeks.
 - ii.** Patient meets ONE of the following (a or b):
 - a.** Patient has not been treated with Eohilia within the previous 6 months; OR
 - b.** According to the prescriber, the patient is experiencing recurrent worsening dysphagia after discontinuing Eohilia therapy; AND
 - F)** The medication is prescribed by or in consultation with an allergist or gastroenterologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Eohilia is not recommended in the following situations:

- 14.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Gastroenterology – Gattex Prior Authorization Policy

- Gattex® (teduglutide subcutaneous injection – Shire)

REVIEW DATE: 06/26/2024

OVERVIEW

Gattex, a glucagon-like peptide-2 (GLP-2) analog, is indicated for the treatment of **short bowel syndrome** in patients ≥ 1 year of age who are dependent on parenteral support.¹

Clinical Efficacy

In a study involving adults ($n = 86$) with short bowel syndrome requiring parenteral support at least 3 days per week, more patients treated with Gattex through Month 6 achieved $\geq 20\%$ reduction in weekly intravenous volume (63% vs. 30% with placebo).¹ The mean reduction in intravenous volume was 4.4 liters with Gattex vs. 2.3 liters with placebo. When treated over an additional 2 years, the mean reduction from baseline was 7.55 liters. Ten patients were weaned off of nutritional support and remained on Gattex therapy. At Week 24 of a pediatric study, 69% of patients ($n = 18/26$) reduced parenteral support volume by at least 20% with Gattex. The mean reduction in intravenous volume was -23 mL/kg/day, a 42% reduction in parenteral support. Three patients were weaned off of parenteral nutritional support.

Safety

Gattex has Warnings and Precautions regarding acceleration of neoplastic growth, colorectal polyps, intestinal obstruction, biliary and pancreatic disease, fluid overload (including congestive heart failure), and potential for increased absorption of concomitant oral medications, particularly those with a narrow therapeutic index.¹ It was approved with a Risk Evaluation and Mitigation Strategy (REMS) program intended to inform healthcare providers and patients about serious risks, including the risks of possible acceleration of neoplastic growth and enhancement of colon polyp growth, gastrointestinal obstruction, and biliary and pancreatic disorders.²

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Gattex. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Gattex as well as the monitoring required for adverse events and long-term efficacy, approval requires Gattex to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Gattex is recommended in those who meet the following criteria:

FDA-Approved Indication

34. Short Bowel Syndrome. Approve for the duration noted if the patient meets ONE of the following (A or B):

- A) Initial Therapy.** Approve for 6 months if the patient meets ALL of the following (i, ii, and iii):
- i.** Patient is ≥ 1 year of age; AND
 - ii.** Patient meets ONE of the following (a or b):
 - a)** Patient is currently receiving parenteral nutrition on 3 or more days per week; OR
 - b)** According to the prescriber, the patient is unable to receive adequate total parenteral nutrition (TPN) required for caloric needs; AND
 - iii.** The medication is prescribed by or in consultation with a gastroenterologist.
- B) Patient is Currently Receiving Gattex.** Approve for 1 year if the patient meets ALL of the following (i, ii, and iii):
- i.** Patient has already received at least 6 months of therapy with Gattex; AND
Note: A patients who has received < 6 months of continuous therapy should be considered under criterion 1A (Initial Therapy).
 - ii.** According to the prescriber, the patient has experienced at least a 20% decrease from baseline in the weekly volume of parenteral nutrition; AND
 - iii.** The medication is prescribed by or in consultation with a gastroenterologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Gattex is not recommended in the following situations:

- 91.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Gaucher Disease – Enzyme Replacement Therapy – Cerezyme Prior Authorization Policy

- Cerezyme® (imiglucerase intravenous infusion – Genzyme)

REVIEW DATE: 04/10/2024; selected revision 07/17/2024

OVERVIEW

Cerezyme, an analogue of β -glucocerebrosidase, is indicated for the treatment of a confirmed diagnosis of **Type 1 Gaucher disease** in patients ≥ 2 years of age that results in at least one of the following: anemia, thrombocytopenia, bone disease, hepatomegaly, or splenomegaly.¹

Disease Overview

Gaucher disease is a rare autosomal recessive, inherited, lysosomal storage disorder caused by a deficiency of the lysosomal enzyme β -glucocerebrosidase.²⁻⁴ Glucocerebrosidase is responsible for the breakdown of glucosylceramide (GluCer) into glucose and ceramide. A deficiency of this enzyme is characterized by an excessive accumulation of GluCer in the visceral organs such as the liver, spleen, and bone marrow. GluCer remains stored within lysosomes causing enlarged lipid-laden macrophages called “Gaucher cells”.

Gaucher disease is classified into three phenotypes (Types 1 through 3).²⁻⁵ Type 1 is a non-neuronopathic variant with asymptomatic or symptomatic clinical manifestations of splenomegaly, hepatomegaly, anemia, thrombocytopenia, skeletal complications, and occasional lung involvement. Type 2 is an acute neuronopathic form characterized by an early onset (3 to 6 months of age) of rapidly progressive neurological disease with visceral manifestations; death generally occurs by the time patients reach 1 to 2 years of age. Type 3 is referred to as a chronic neuronopathic form and characterized by a later onset. Patients present with neurological, hematological, and visceral symptoms. Type 1 is most prevalent in the Western world, accounting for an estimated 94% of patients with Gaucher disease.^{2,6} Types 2 and 3 represent $< 1\%$ and 5% , respectively, in Europe, North America, and Israel.^{2,5} The diagnosis of Gaucher disease is established by demonstrating deficient β -glucocerebrosidase activity in leukocytes or fibroblasts, or mutations in the glucocerebrosidase gene.^{7,8}

Guidelines

Treatment guidelines for Type 1 Gaucher disease (non-neuronopathic form) recommend initiating enzyme replacement therapy (ERT) in patients with significant and/or progressive disease.^{9,10} Additionally, ERT should be initiated immediately in all patients with Type 3 Gaucher disease (chronic neuronopathic form).¹¹ Guidelines note that there is no evidence that ERT has reversed, stabilized, or slowed the progression of neurological involvement. However, ERT ameliorates systemic involvement (skeletal deterioration, visceromegaly, hematological abnormalities) in non-neuronopathic as well as chronic neuronopathic disease, ultimately enhancing the quality of life. Additionally, it is noted that higher doses may be needed to control visceral symptoms associated with chronic neuronopathic disease.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Cerezyme. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Cerezyme as well as the monitoring required for adverse events and long-term efficacy, approval requires Cerezyme to be prescribed by or in consultation with a physician who specializes in the condition being treated.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Cerezyme is recommended in those who meet one of the following criteria:

FDA-Approved Indication

35. Gaucher Disease – Type 1. Approve for 1 year if the patient meets ALL of the following (A, B, and C):

Note: Type 1 Gaucher disease is also known as non-neuronopathic Gaucher disease.

A) Patient is ≥ 2 years of age; AND

B) The diagnosis is established by ONE of the following (i or ii):

i. Demonstration of deficient β -glucocerebrosidase activity in leukocytes or fibroblasts; OR

ii. Molecular genetic testing documenting biallelic pathogenic variants in the glucocerebrosidase (GBA) gene; AND

C) Cerezyme is prescribed by or in consultation with a geneticist, endocrinologist, a metabolic disorder sub-specialist, or a physician who specializes in the treatment of lysosomal storage disorders.

Other Uses with Supportive Evidence

36. Gaucher Disease – Type 3. Approve for 1 year if the patient meets ALL of the following (A, B, C, and D):

Note: Type 3 Gaucher disease is also known as chronic neuronopathic Gaucher disease.

A) Patient is ≥ 2 years of age; AND

B) The diagnosis is established by ONE of the following (i or ii):

i. Demonstration of deficient β -glucocerebrosidase activity in leukocytes or fibroblasts; OR

ii. Molecular genetic testing documenting biallelic pathogenic variants in the glucocerebrosidase (GBA) gene; AND

C) The patient meets BOTH of the following (i and ii):

i. Medication is not being used for the management of neurological manifestations; AND

Note: Examples of neurological manifestations may include abnormal ocular movement, auditory impairment, cognitive impairment, and seizures.

ii. Medication is being used for the management of impaired growth, hematologic, or visceral symptoms; AND

Note: Examples of visceral symptoms include splenomegaly and hepatomegaly. Examples of hematologic symptoms include anemia and thrombocytopenia.

D) Cerezyme is prescribed by or in consultation with a geneticist, endocrinologist, a metabolic disorder sub-specialist, or a physician who specializes in the treatment of lysosomal storage disorders.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Cerezyme is not recommended in the following situations:

92. Concomitant Use with Other Approved Therapies for Gaucher Disease. Concomitant use with other treatments approved for Gaucher disease has not been evaluated. Of note, examples of medications approved for Gaucher disease include Cerdelga (eliglustat capsules), Elelyso (taliglucerase alfa intravenous infusion), Vpriv (velaglucerase alfa intravenous infusion), and Zavesca (miglustat capsules).

04/10/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

93. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Gaucher Disease – Enzyme Replacement Therapy – Elelyso Prior Authorization Policy

- Elelyso® (taliglucerase intravenous infusion – Pfizer)

REVIEW DATE: 04/10/2024; selected revision 07/17/2024

OVERVIEW

Elelyso, an analogue of β -glucocerebrosidase, is indicated for the treatment of a confirmed diagnosis of **Type 1 Gaucher disease** in patients ≥ 4 years of age.¹

Disease Overview

Gaucher disease is a rare autosomal recessive, inherited, lysosomal storage disorder caused by a deficiency of the lysosomal enzyme β -glucocerebrosidase.²⁻⁴ Glucocerebrosidase is responsible for the breakdown of glucosylcerebroside (GluCer) into glucose and ceramide. A deficiency of this enzyme is characterized by an excessive accumulation of GluCer in the visceral organs such as the liver, spleen, and bone marrow. GluCer remains stored within lysosomes causing enlarged lipid-laden macrophages called “Gaucher cells”.

Gaucher disease is classified into three phenotypes (Types 1 through 3).²⁻⁵ Type 1 is a non-neuronopathic variant with asymptomatic or symptomatic clinical manifestations of splenomegaly, hepatomegaly, anemia, thrombocytopenia, skeletal complications, and occasional lung involvement. Type 2 is an acute neuronopathic form characterized by an early onset (3 to 6 months of age) of rapidly progressive neurological disease with visceral manifestations; death generally occurs by the time patients reach 1 to 2 years of age. Type 3 is referred to as a chronic neuronopathic form and characterized by a later onset. Patients present with neurological, hematological, and visceral symptoms. Type 1 is most prevalent in the Western world, accounting for an estimated 94% of patients with Gaucher disease.^{2,6} Types 2 and 3 represent < 1% and 5%, respectively, in Europe, North America, and Israel.^{2,5} The diagnosis of Gaucher disease is established by demonstrating deficient β -glucocerebrosidase activity in leukocytes or fibroblasts, or mutations in the glucocerebrosidase gene.^{7,8}

Guidelines

Treatment guidelines for Type 1 Gaucher disease (non-neuronopathic form) recommend initiating enzyme replacement therapy (ERT) in patients with significant and/or progressive disease.^{9,10} Additionally, ERT should be initiated immediately in all patients with Type 3 Gaucher disease (chronic neuronopathic form).¹¹ Guidelines note that there is no evidence that ERT has reversed, stabilized, or slowed the progression of neurological involvement. However, ERT ameliorates systemic involvement (skeletal deterioration, visceromegaly, hematological abnormalities) in non-neuronopathic as well as chronic neuronopathic disease, ultimately enhancing the quality of life. Additionally, it is noted that higher doses may be needed to control visceral symptoms associated with chronic neuronopathic disease.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Elelyso. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Elelyso as well as the monitoring required for adverse events and long-term efficacy, approval requires Elelyso to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Elelyso is recommended in those who meet one of the following criteria:

FDA-Approved Indication

37. Gaucher Disease – Type 1. Approve for 1 year if the patient meets ALL of the following (A, B, and C):

Note: Type 1 Gaucher disease is also known as non-neuronopathic Gaucher disease.

A) Patients is ≥ 4 years of age; AND

B) The diagnosis is established by ONE of the following (i or ii):

i. Demonstration of deficient β -glucocerebrosidase activity in leukocytes or fibroblasts; OR

ii. Molecular genetic testing documenting biallelic pathogenic variants in the glucocerebrosidase (*GBA*) gene; AND

C) Elelyso is prescribed by or in consultation with a geneticist, endocrinologist, a metabolic disorder sub-specialist, or a physician who specializes in the treatment of lysosomal storage disorders.

Other Uses with Supportive Evidence

38. Gaucher Disease – Type 3. Approve for 1 year if the patient meets ALL of the following (A, B, C, and D):

Note: Type 3 Gaucher disease is also known as chronic neuronopathic Gaucher disease.

A) Patient is ≥ 4 years of age; AND

B) The diagnosis is established by ONE of the following (i or ii):

i. Demonstration of deficient β -glucocerebrosidase activity in leukocytes or fibroblasts; OR

ii. Molecular genetic testing documenting biallelic pathogenic variants in the glucocerebrosidase (*GBA*) gene; AND

C) The patient meets BOTH of the following (i and ii):

i. Medication is not being used for the management of neurological manifestations; AND

Note: Examples of neurological manifestations may include abnormal ocular movement, auditory impairment, cognitive impairment, and seizures.

ii. Medication is being used for the management of impaired growth, hematologic, or visceral symptoms.

Note: Examples of visceral symptoms include splenomegaly and hepatomegaly. Examples of hematologic symptoms include anemia and thrombocytopenia.

D) Elelyso is prescribed by or in consultation with a geneticist, endocrinologist, a metabolic disorder sub-specialist, or a physician who specializes in the treatment of lysosomal storage disorders.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage for Elelyso is not recommended in the following situations:

- 94. Concomitant Use with Other Approved Therapies for Gaucher Disease.** Concomitant use with other treatments approved for Gaucher disease has not been evaluated. Of note, examples of medications approved for Gaucher disease include Cerdelga (eliglustat capsules), Cerezyme (imiglucerase intravenous infusion), Vpriv (velaglucerase alfa intravenous infusion), and Zavesca (miglustat capsules).
- 95.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

approval requires Vpriv to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Vpriv is recommended in those who meet one of the following criteria:

FDA-Approved Indication

39. Gaucher Disease – Type 1. Approve for 1 year if the patient meets ALL of the following (A , B, and C):

Note: Type 1 Gaucher disease is also known as non-neuronopathic Gaucher disease.

A) Patient is ≥ 4 years of age; AND

B) The diagnosis is established by ONE of the following (i or ii):

i. Demonstration of deficient β -glucocerebrosidase activity in leukocytes or fibroblasts; OR

ii. Molecular genetic testing documenting biallelic pathogenic variants in the glucocerebrosidase (GBA) gene; AND

C) Vpriv is prescribed by or in consultation with a geneticist, endocrinologist, a metabolic disorder sub-specialist, or a physician who specializes in the treatment of lysosomal storage disorders.

Other Uses with Supportive Evidence

1. Gaucher Disease – Type 3. Approve for 1 year if the patient meets ALL of the following (A, B, C, and D):

Note: Type 3 Gaucher disease is also known as chronic neuronopathic Gaucher disease.

A) Patient is ≥ 4 years of age; AND

B) The diagnosis is established by ONE of the following (i or ii):

i. Demonstration of deficient β -glucocerebrosidase activity in leukocytes or fibroblasts; OR

ii. Molecular genetic testing documenting biallelic pathogenic variants in the glucocerebrosidase (GBA) gene; AND

C) The patient meets BOTH of the following (i and ii):

i. Medication is not being used for the management of neurological manifestations; AND

Note: Examples of neurological manifestations may include abnormal ocular movement, auditory impairment, cognitive impairment, and seizures.

ii. Medication is being used for the management of impaired growth, hematologic, or visceral symptoms; AND

Note: Examples of visceral symptoms include splenomegaly and hepatomegaly. Examples of hematologic symptoms include anemia and thrombocytopenia.

D) Vpriv is prescribed by or in consultation with a geneticist, endocrinologist, a metabolic disorder sub-specialist, or a physician who specializes in the treatment of lysosomal storage disorders.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Vpriv is not recommended in the following situations:

96. Concomitant Use with Other Approved Therapies for Gaucher Disease. Concomitant use with other treatments approved for Gaucher disease has not been evaluated. Of note, examples of medications approved for Gaucher disease include Cerdelga (eliglustat capsules), Elelyso (taliglucerase

alfa intravenous infusion), Cerezyme (imiglucerase intravenous infusion), and Zavesca (miglustat capsules).

97. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Gaucher Disease – Substrate Reduction Therapy – Cerdelga Prior Authorization Policy

- Cerdelga® (eliglustat capsules – Genzyme)

REVIEW DATE: 05/29/2024; selected revision 08/14/2024

OVERVIEW

Cerdelga, a glucosylceramide synthase inhibitor, is indicated for the long-term treatment of adults with **Gaucher disease type 1** who are cytochrome P450 2D6 extensive metabolizers, intermediate metabolizers, or poor metabolizers as detected by an FDA-cleared test.¹

Disease Overview

Gaucher disease is caused by a deficiency in the lysosomal enzyme β -glucocerebrosidase.¹ This enzyme is responsible for the breakdown of glucosylceramide into glucose and ceramide. In Gaucher disease, deficiency of the enzyme β -glucocerebrosidase results in the accumulation of glucosylceramide substrate in the lysosomal compartment of macrophages, giving rise to foam cells or “Gaucher cells.” Cerdelga is a specific inhibitor of the enzyme glucosylceramide synthase, which is responsible for producing the substrate glucosylceramide; hence Cerdelga functions as a substrate reduction therapy.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Cerdelga. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Cerdelga as well as the monitoring required for adverse events and long-term efficacy, approval requires Cerdelga to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Cerdelga is recommended in those who meet the following criteria:

FDA-Approved Indication

- 40. Gaucher Disease Type 1.** Approve for 1 year if the patient meets ALL of the following (A, B, and C):
- A) Patient is a cytochrome P450 2D6 extensive metabolizer, intermediate metabolizer, or poor metabolizer as detected by an approved test; AND
 - B) The diagnosis is established by ONE of the following (i or ii):
 - i. Demonstration of deficient beta-glucocerebrosidase activity in leukocytes or fibroblasts; OR
 - ii. Molecular genetic test documenting biallelic pathogenic glucocerebrosidase (GBA) gene variants; AND
 - C) The medication is prescribed by or in consultation with a geneticist, endocrinologist, metabolic disorder subspecialist, or a physician who specializes in the treatment of Gaucher disease or related disorders.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Cerdelga is not recommended in the following situations:

- 15. Concomitant Use with Other Approved Therapies for Gaucher Disease.** Concomitant use with other treatments approved for Gaucher disease has not been evaluated. Of note, examples of medications approved for Gaucher disease include Cerezyme (imiglucerase intravenous infusion), Elelyso (taliglucerase alfa intravenous infusion), Vpriv (velaglucerase alfa intravenous infusion), and Zavesca (miglustat capsules).
- 16.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Gaucher Disease – Substrate Reduction Therapy – Miglustat Prior Authorization Policy

- Zavesca® (miglustat capsules – Actelion, generic)

REVIEW DATE: 05/29/2024; selected revision 08/14/2024, 10/30/2024

OVERVIEW

Miglustat capsules (Zavesca, generic), a glucosylceramide synthase inhibitor, is indicated as monotherapy for the treatment of mild to moderate **Gaucher disease type 1** in adults for whom enzyme replacement therapy is not a therapeutic option (e.g., due to allergy, hypersensitivity, or poor venous access).¹

Disease Overview

Gaucher disease is caused by a deficiency in the lysosomal enzyme β -glucocerebrosidase.² This enzyme is responsible for the breakdown of glucosylceramide into glucose and ceramide. In Gaucher disease, deficiency of the enzyme β -glucocerebrosidase results in the accumulation of glucosylceramide substrate in lysosomal compartment of macrophages, giving rise to foam cells or “Gaucher cells.” Miglustat is a specific inhibitor of the enzyme glucosylceramide synthase, which is responsible for producing the substrate glucosylceramide.¹ By functioning as a substrate reduction therapy, miglustat allows the residual activity of the deficient glucocerebrosidase enzyme to be more effective.

Other Uses with Supportive Evidence

Although not FDA approved, miglustat has been used off-label for the treatment of Niemann-Pick disease Type C (NPC). NPC is an autosomal recessive, slowly progressive ultra-rare, lysosomal storage disorder.³ It is caused by variants in either the *NPC1* (90% to 95%) or *NPC2* (5%) gene and yields deficient function of the corresponding proteins that normally bind and transport cholesterol.⁴ Essentially, NPC results from a combination of toxic lipid accumulation in the lysosomes and a relative deficiency of necessary cholesterol in the rest of the cell. The lysosomal dysfunction in NPC leads to an accumulation of lipids in the brain, liver, and spleen. The clinical manifestations vary with age of onset and range from a neonatal rapidly progressive fatal disorder to an adult-onset chronic neurodegenerative disease.⁵ Consensus clinical management guidelines for NPC have been developed by the International Niemann-Pick Disease Registry (INPDR) project (2018). Molecular genetic analysis of the *NPC1* and *NPC2* genes are required to confirm the diagnosis of NPC. It is recommended that all patients with a confirmed diagnosis of NPC should be considered for miglustat. However, miglustat is not recommended in patients with profound neurological disease since assessment of improvement with therapy would not be feasible.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of miglustat capsules. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with miglustat capsules as well as the monitoring required for adverse events and long-term efficacy, approval requires miglustat capsules to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

05/29/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Coverage of miglustat capsules is recommended in those who meet one of the following criteria:

FDA-Approved Indication

- 41. Gaucher Disease Type 1.** Approve for 1 year if the patient meets BOTH of the following (A and B):
- A) The diagnosis is established by ONE of the following (i or ii):
 - i. Demonstration of deficient beta-glucocerebrosidase activity in leukocytes or fibroblasts; OR
 - ii. Molecular genetic test showing biallelic pathogenic glucocerebrosidase (*GBA*) gene variants; AND
 - B) The medication is prescribed by or in consultation with a geneticist, endocrinologist, metabolic disorder subspecialist, or a physician who specializes in the treatment of Gaucher disease or related disorders.

Other Uses with Supportive Evidence

- 2. Niemann-Pick Disease Type C (NPC).** Approve for 1 year if the patient meets ALL of the following (A, B, and C):
- A) Patient is ≥ 2 years of age; AND
 - B) The diagnosis is established by a molecular genetic test showing biallelic pathogenic variants in either the *NPC1* or *NPC2* gene; AND
 - C) The medication is prescribed by or in consultation with a geneticist, endocrinologist, metabolic disorder subspecialist, or a physician who specializes in the treatment of NPC or related disorders.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of miglustat capsules is not recommended in the following situations:

- 17. Concomitant Use with Other Approved Therapies for Gaucher Disease.** Concomitant use with other treatments approved for Gaucher disease has not been evaluated. Of note, examples of medications approved for Gaucher disease include Cerezyme (imiglucerase intravenous infusion), Elelyso (taliglucerase alfa intravenous infusion), Vpriv (velaglucerase alfa intravenous infusion), and Cerdelga (eliglustat capsules).
- 18.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Gonadotropin-Releasing Hormone Agonist – Synarel Prior Authorization Policy

- Synarel® (nafarelin acetate nasal solution – Pfizer)

REVIEW DATE: 12/20/2023

OVERVIEW

Synarel, a gonadotropin-releasing hormone (GnRH) agonist, is indicated for the following:¹

- **Central precocious puberty**, treatment in children of both sexes.
- **Endometriosis management**, including pain relief and reduction of endometriotic lesions. Experience with Synarel for this indication is limited to women ≥ 18 years of age treated for 6 months.

Guidelines

GnRH agonists are the standard of care for the treatment of central precocious puberty.²⁻⁴ The European Society for Paediatric Endocrinology and the Lawson Wilkins Pediatric Endocrine Society convened a consensus conference to review the use of GnRH agonists in pediatric patients with central precocious puberty (2009).² The panel noted that the available GnRH agonists (including nafarelin) are effective despite different routes of administration, dosing, and duration of action. In addition, the various GnRH agonists are well-tolerated in children and adolescents. An update by an International Consortium (2019) notes the lack of prospective comparative studies to establish differences in efficacy (if any) among the various GnRH agonists.³ Discontinuation of GnRH agonist therapy should be individualized, based on the patient's readiness for resumption of puberty, recent growth rates, and shifts in height prediction.

The American College of Obstetricians and Gynecologists (ACOG) practice bulletin on the management of endometriosis (2010, reaffirmed 2018) notes that empiric treatment with a GnRH agonist is appropriate after an appropriate pretreatment evaluation (to exclude other causes of chronic pelvic pain) and failure of initial treatment with oral contraceptives and non-steroidal anti-inflammatory drugs.⁵

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Synarel. All approvals are provided for 1 year in duration unless otherwise noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Synarel is recommended in those who meet one of the following criteria:

FDA-Approved Indications

16. Central Precocious Puberty. Approve for 1 year.

12/20/2023

© 2023. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

17. Endometriosis. Approve for 6 months if the patient meets the following (A and B):

- a) Patient is ≥ 18 years of age; AND
- b) Patient has tried one of the following, unless contraindicated (i, ii, or iii):
 - i. A contraceptive; OR

Note: Examples of contraceptives include combination oral contraceptives, levonorgestrel-releasing intrauterine systems [e.g., Mirena[®], Liletta[®]].

- ii. An oral progesterone (e.g., norethindrone tablets); OR
- iii. A depo-medroxyprogesterone injection.

Note: An exception to the requirement for a trial of the above therapies can be made if the patient has previously used a gonadotropin-releasing hormone (GnRH) agonist (e.g., Lupron Depot) or antagonist (e.g., Orilissa) for endometriosis.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Synarel is not recommended in the following situations:

- 3. **Peripheral Precocious Puberty (Also Known as Gonadotropin-Releasing Hormone-Independent Precocious Puberty).** Children with peripheral precocious puberty do not respond to GnRH agonist therapy.² Treatment is directed at removing or blocking the production and/or response to the excess sex steroids, depending on the cause (e.g., surgically removing human chorionic gonadotropin-secreting tumors or using glucocorticoids to treat defects in adrenal steroidogenesis [such as classic congenital adrenal hyperplasia]).
- 4. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Gonadotropin-Releasing Hormone Agonists – Central Precocious Puberty Prior Authorization Policy

- Fensolvi® (leuprolide acetate subcutaneous injection, extended-release – Tolmar)
- Lupron Depot-Ped® (leuprolide acetate depot intramuscular injection – AbbVie)
- Triptodur™ (triptorelin intramuscular injection, extended-release – Azurity)

REVIEW DATE: 10/23/2024

OVERVIEW

Fensolvi, Lupron Depot-Ped, and Triptodur are gonadotropin-releasing hormone (GnRH) agonists indicated for the treatment of **central precocious puberty** in pediatric patients.¹⁻³ Fensolvi is administered by a subcutaneous injection and both Lupron Depot-Ped and Triptodur are administered by intramuscular injection. Fensolvi is administered once every 6 months, Lupron Depot-Ped is administered once a month, once every 3 months (or 12 weeks), or once every 6 months (24 weeks), and Triptodur is administered once every 24 weeks.

GnRH agonists can also be used off-label for the treatment of **gender-dysphoric/gender-incongruent persons** to suppress physical changes of puberty and gonadal function.^{7,8} Pubertal hormonal suppression should typically be initiated after the adolescent first exhibits physical changes of puberty (Tanner stages G2/B2). Long-acting GnRH analogs are the currently preferred treatment option. An advantage to using a GnRH analog is that the effects can be reversed; pubertal suppression can be discontinued if the individual no longer wishes to transition. Upon discontinuation of therapy, spontaneous pubertal development has been shown to resume. GnRH analogs can also be used in patients during late puberty to suppress the hypothalamic-pituitary-gonadal axis to allow for lower doses of cross-sex hormones.⁹ In addition to use in adolescents, GnRH analog therapy is also used in adults, particularly male-to-female patients.¹⁰

Guidelines

The standard of care for central precocious puberty is GnRH agonists.⁴⁻⁶ The European Society for Paediatric Endocrinology and the Lawson Wilkins Pediatric Endocrine Society convened a consensus conference to review the use of GnRH agonists in pediatric patients with central precocious puberty (2009).⁴ The panel noted that the available GnRH agonists (including leuprolide and triptorelin) are effective despite different routes of administration, dosing, and duration of action. In addition, the various GnRH agonists are well-tolerated in children and adolescents. An update by an International Consortium (2019) notes the lack of prospective comparative studies to establish differences in efficacy (if any) among the various GnRH agonists.⁵ The Consortium does not prefer one GnRH agonist over another. Discontinuation of GnRH agonist therapy should be individualized, based on the patient's readiness for resumption of puberty, recent growth rates, and shifts in height prediction.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of gonadotropin-releasing hormone agonists (Fensolvi, Lupron Depot-Ped, and Triptodur). All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of gender-dysphoric/gender-incongruent persons treated with Fensolvi, Lupron Depot-Ped, or Triptodur as well as the monitoring required for adverse events and long-term efficacy, approval requires that the product be prescribed by or in consultation with a physician who specializes in this condition.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of a gonadotropin-releasing hormone agonist (Fensolvi, Lupron Depot-Ped, and Triptodur) is recommended in those who meet one of the following criteria:

FDA-Approved Indication

20. Central Precocious Puberty. Approve the requested gonadotropin-releasing hormone agonist for 1 year.

Other Uses with Supportive Evidence

21. Gender-Dysphoric/Gender-Incongruent Persons; Persons Undergoing Gender Reassignment (Female-To-Male or Male-To-Female). Approve the requested gonadotropin-releasing hormone agonist for 1 year if prescribed by or in consultation with an endocrinologist or a physician who specializes in the treatment of transgender patients.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of a gonadotropin-releasing hormone agonist (Fensolvi, Lupron Depot-Ped, and Triptodur) is not recommended in the following situations:

19. Peripheral Precocious Puberty (Also Known as GnRH-Independent Puberty). Children with peripheral precocious puberty do not respond to GnRH agonist therapy.⁴ Treatment is directed at removing or blocking the production and/or response to the excess sex steroids, depending on the cause (e.g., surgically removing human chorionic gonadotropin-secreting tumors or using glucocorticoids to treat defects in adrenal steroidogenesis [such as classic congenital adrenal hyperplasia]).

20. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

- POLICY:** Gonadotropin-Releasing Hormone Agonists – Implants Prior Authorization Policy
- Supprelin® LA (histrelin acetate subcutaneous implant – Endo)
 - Vantas® (histrelin acetate subcutaneous implant – Endo [discontinued])
 - Zoladex® (goserelin acetate subcutaneous implant – TerSera Therapeutics)

REVIEW DATE: 02/21/2024

OVERVIEW

Supprelin LA, Vantas, and Zoladex are gonadotropin-releasing hormone (GnRH) agonist implants.¹⁻⁴

Supprelin LA is indicated for the treatment of **central precocious puberty** in children.¹

Vantas is indicated for the palliative treatment of **advanced prostate cancer**.² Although Vantas is not indicated for use in children with central precocious puberty, it contains the same chemical entity as Supprelin LA and can be used for this condition. Endo discontinued the manufacturing of Vantas as of 9/21/2021.¹⁰

Zoladex is indicated for the following conditions.^{3,4} Zoladex 3.6 mg (equivalent to 3.8 mg goserelin acetate) is approved for all the diagnoses below. Zoladex 10.8 mg (equivalent to 11.3 mg goserelin acetate) is only indicated for prostate cancer.

- **Breast cancer**, palliative treatment of advanced breast cancer in pre- and perimenopausal women (Zoladex 3.6 mg implant only).
- **Endometrial-thinning**, use as an endometrial-thinning agent prior to endometrial ablation for dysfunctional uterine bleeding (Zoladex 3.6 mg implant only).
- **Endometriosis**, including pain relief and reduction of endometriotic lesions for the duration of therapy (Zoladex 3.6 mg implant only). Labeling notes that experience with Zoladex for this indication has been limited to women ≥ 18 years of age.³
- **Prostate cancer**, in combination with flutamide for the management of locally confined Stage T2b-T4 (Stage B2-C).
- **Prostate cancer**, advanced carcinoma or palliative treatment.

Guidelines

The GnRH agonists are addressed in treatment guidelines:

- **Breast cancer:** The National Comprehensive Cancer Network (NCCN) breast cancer guidelines (version 1.2024 – January 25, 2024) note that candidates for ovarian suppression plus endocrine therapy include: 1) premenopausal women, and 2) endocrine sensitive tumors with high enough recurrence risk where the additional absolute decrease in recurrence compared with tamoxifen alone is worth the additional toxicity (young age, high-grade tumor, lymph node involvement).⁵ Goserelin doses for breast cancer are recommended at 3.6 mg subcutaneous every 4 weeks or 10.8 mg subcutaneous every 12 weeks. Guidelines also note that GnRH agonists (e.g., goserelin) administered prior to initiating chemotherapy protect against ovarian failure and reduce the risk of early menopause. Ovarian suppression may be recommended in patients who are premenopausal at diagnosis.
- **Central precocious puberty**, also known as gonadotropin-dependent precocious puberty, is caused by early maturation of the hypothalamic-pituitary-gonadal axis.⁶ The standard of care for central precocious puberty is GnRH agonists. The European Society for Paediatric Endocrinology

02/21/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

and the Lawson Wilkins Pediatric Endocrine Society convened a consensus conference (2009) to review the use of GnRH agonists in pediatric patients with central precocious puberty.⁷ The panel noted that the available GnRH agonists (including leuprolide, triptorelin, and histrelin implants) are effective despite different routes of administration, dosing, and duration of action. An update by the International Consortium (2019) reiterates the use of GnRH agonists (e.g., leuprolide, triptorelin, and histrelin implants) for the treatment of central precocious puberty.⁸ GnRH agonists are generally well-tolerated in children and adolescents.

- **Head and neck cancer – salivary gland tumors:** The NCCN head and neck cancer guidelines (version 2.2024 – December 08, 2023) notes that goserelin (category 2B) is useful for androgen receptor positive salivary gland tumors which are recurrent, unresectable, or metastatic.^{11,13}
- **Ovarian cancer, including fallopian tube cancer and primary peritoneal cancer:** The NCCN ovarian cancer guidelines (version 1.2024 – January 17, 2024) notes goserelin as other hormone therapy options for endometrioid carcinoma, low-grade serous carcinoma, and malignant sex cord stromal tumors.^{11,14}
- **Prostate cancer:** The NCCN prostate cancer guidelines (version 4.2023 – September 7, 2023) list goserelin, leuprolide, and triptorelin as androgen deprivation therapy options for use in various settings: clinically localized disease, regional disease, prostate specific antigen persistence/recurrence after radical prostatectomy or external beam radiation therapy (castration-sensitive disease), and metastatic castration-sensitive disease.⁹
- **Uterine cancer:** The NCCN uterine neoplasm guidelines (version 1.2024 – September 20, 2023) notes that GnRH analogs are included as a category 2B option for endometrial stromal sarcoma, adenosarcoma without sarcomatous overgrowth, and estrogen receptor-progesterone receptor positive uterine sarcomas.^{11,12}

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Supprelin LA, Vantas, and Zoladex. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Vantas and Zoladex, as well as the monitoring required for adverse events and long-term efficacy, approval requires these agents to be prescribed by or in consultation with a physician who specializes in the condition being treated. Note that as with Supprelin LA, when Vantas is prescribed for central precocious puberty, it does not need to be prescribed by or in consultation with a specialist.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

I. Coverage of Supprelin LA is recommended in patients who meet the following criteria:

FDA-Approved Indication

1. **Central Precocious Puberty.** Approve for 1 year.

II. Coverage of Vantas is recommended in patients who meet one of the following criteria:

FDA-Approved Indication

02/21/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

1. **Prostate Cancer.** Approve for 1 year if the medication is prescribed by or in consultation with an oncologist.

Other Uses with Supportive Evidence

2. **Central Precocious Puberty.** Approve for 1 year.

III. Coverage of Zoladex is recommended in patients who meet one of the following criteria:

FDA-Approved Indications

1. **Abnormal Uterine Bleeding.** Approve Zoladex 3.6 mg for 2 months if the patient meets the following (A and B):
 - A) Zoladex is used as an endometrial-thinning agent prior to endometrial ablation; AND
 - B) The medication is prescribed by or in consultation with an obstetrician-gynecologist or a healthcare practitioner who specializes in the treatment of women's health.
2. **Breast Cancer.** Approve Zoladex 3.6 mg or 10.8 mg for 1 year if the medication is prescribed by or in consultation with an oncologist.
3. **Endometriosis.** Approve Zoladex 3.6 mg for 6 months if the patient meets the following (A and B):
 - A) Patient is ≥ 18 years of age; AND
 - B) The medication is prescribed by or in consultation with an obstetrician-gynecologist or a healthcare practitioner who specializes in the treatment of women's health.
4. **Head and Neck Cancer – Salivary Gland Tumors.** Approve Zoladex 3.6 mg for 1 year if the patient meets the following (A, B, and C):
 - A) Patient has recurrent, unresectable, or metastatic disease; AND
 - B) Patient has androgen receptor-positive disease; AND
 - C) The medication is prescribed by or in consultation with an oncologist.
5. **Ovarian Cancer, including Fallopian Tube Cancer and Primary Peritoneal Cancer.** Approve Zoladex 3.6 mg for 1 year if the medication is prescribed by or in consultation with an oncologist.
6. **Prostate Cancer.** Approve Zoladex 3.6 mg or 10.8 mg for 1 year if the medication is prescribed by or in consultation with an oncologist.
7. **Uterine Cancer.** Approve Zoladex 3.6 mg for 1 year if the medication is prescribed by or in consultation with an oncologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Supprelin LA, Vantas, and Zoladex is not recommended in the following situations:

21. **Peripheral Precocious Puberty (also known as GnRH-independent precocious puberty).**
Children with peripheral precocious puberty do not respond to GnRH agonist therapy.⁸ Treatment is directed at removing or blocking the production and/or response to the excess sex steroids, depending on the cause (e.g., surgically removing human chorionic gonadotropin-secreting tumors or using

glucocorticoids to treat defects in adrenal steroidogenesis [such as classic congenital adrenal hyperplasia]).

2. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Gonadotropin-Releasing Hormone Agonists – Injectable Long-Acting Products Prior Authorization Policy

- Lupron Depot® (leuprolide acetate suspension for intramuscular injection – AbbVie)
- Lupaneta Pack® (leuprolide acetate for depot suspension; norethindrone acetate tablets co-packaged for intramuscular use and oral use, respectively – AbbVie) [discontinued]

REVIEW DATE: 02/21/2024

Overview

Lupaneta Pack is indicated for initial management of the painful symptoms of **endometriosis** and for management of recurrence of symptoms.^{1,2} Lupaneta Pack was discontinued in 2021.

Lupron Depot (3.75 mg intramuscular (IM) injection every month, 11.25 mg IM injection every 3 months) is indicated for the following conditions:^{3,4}

- **Anemia caused by uterine leiomyomata** (fibroids), preoperative hematologic improvement in women for whom 3 months of hormonal suppression is deemed necessary. (Lupron Depot in combination with iron therapy).
- **Endometriosis**, including pain relief and reduction of endometriotic lesions (Lupron Depot monotherapy).
- **Endometriosis**, initial management of the painful symptoms of endometriosis and management of recurrence of symptoms (Lupron Depot in combination with norethindrone acetate 5 mg daily).

Lupron Depot (7.5 mg IM injection every month, 22.5 mg IM injection every 3 months, 30 mg IM injection every 4 months, and 45 mg IM injection every 6 months) is indicated for the palliative treatment of **advanced prostate cancer**.⁵

Duration of Treatment:

- Lupaneta Pack: Initial treatment course is limited to 6 months; a single retreatment course of up to 6 months is allowed. Total duration of treatment is limited to 12 months.^{1,2}
- Lupron Depot 3.75 mg and 11.25 mg:^{3,4}
 - Endometriosis: For the first 6 months of treatment, Lupron Depot may be used as monotherapy or in combination with norethindrone acetate. If retreatment is needed, Lupron Depot must be used in combination with norethindrone acetate (for 6 months). Total duration of treatment is limited to 12 months.
 - Uterine leiomyomata (fibroids): Recommended duration of treatment is up to 3 months.
- Lupron Depot 7.5 mg, 22.5 mg, 30 mg, and 45 mg: Labeling does not specify a treatment duration.

Guidelines

Abnormal Uterine Bleeding/Uterine Leiomyomata (Fibroids)

The American College of Obstetricians and Gynecologists (ACOG) [2021] practice bulletin regarding the management of symptomatic uterine leiomyomas discuss that gonadotropin-releasing hormone (GnRH) agonists (either with or without add-back hormonal therapy) are recommended for bleeding associated with fibroids, uterine enlargement associated with fibroids, and as a bridge to other treatment strategies (such as surgical management, menopause, or other medical therapies).⁶ Add-back hormonal therapy (such as low-dose estrogen or progestin, or both), may help mitigate the hypoestrogenic effects of GnRH agonists, such

02/21/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

as decreased bone mineral density. The guidelines state that the type, dose, and route of delivery of add-back therapy depend on patient preference and the severity of symptoms.

GnRH agonists can also be used for acute abnormal uterine bleeding with an aromatase inhibitor or antagonist to prevent initial estrogen flare and for the treatment of heavy menstrual bleeding caused by leiomyoma-associated hormonal imbalance.⁷ A clinical practice guideline from the Society of Obstetricians and Gynaecologists of Canada notes that leuprolide acetate or combined hormonal contraception should be considered highly effective in preventing abnormal uterine bleeding when initiated prior to cancer treatment in premenopausal women at risk of thrombocytopenia.⁸ The ACOG committee opinion on options for prevention and management of menstrual bleeding in adolescent patients undergoing cancer treatment states that GnRH agonists are an option for menstrual suppression.⁹

Endometriosis

According to the ACOG practice bulletin on the management of endometriosis (2010, reaffirmed 2018), empiric therapy with a 3-month course of a GnRH agonist is appropriate after an appropriate pretreatment evaluation (to exclude other causes of chronic pelvic pain) and failure of initial treatment with oral contraceptives and nonsteroidal anti-inflammatory drugs.¹⁰ The ACOG committee opinion on dysmenorrhea and endometriosis in the adolescent (2018) notes that patients with endometriosis who have pain after conservative surgical therapy and suppressive hormonal therapy may benefit from at least 6 months of GnRH agonist therapy with add-back medicine.¹¹

Other Uses With Supportive Evidence

ACOG practice guideline (2023) suggests GnRH agonists with adjunctive combined hormonal add-back therapy for adults with severe, refractory premenstrual symptoms.²⁷ Premenstrual disorders include the conditions of premenstrual syndrome (PMS) and premenstrual dysphoric disorder (PMDD). The symptoms associated with these conditions can be physical and/or affective and may interfere with daily functioning. GnRH agonists are not recommended as first-line therapy and should be reserved for adult patients who have severe symptoms. GnRH agonists are not generally used to treat premenstrual symptoms in adolescents because of the lack of efficacy data in this population and concern for long-term effects on bone health. ACOG recommends selective serotonin reuptake inhibitors for the management of affective premenstrual symptoms and combined oral contraceptives for the management of overall premenstrual symptoms.

The Endocrine Society Guideline (2017) for the Treatment of Gender-Dysphoric/Gender-Incongruent Persons note that persons who fulfill criteria for treatment and who request treatment should initially undergo treatment to suppress physical changes of puberty.¹² Pubertal hormonal suppression should typically be initiated after the adolescent first exhibits physical changes of puberty (Tanner stages G2/B2). However, there may be compelling reasons to initiate hormone treatment before the age of 16 years in some adolescents. The guidelines note suppression of pubertal development and gonadal function can be effectively achieved via gonadotropin suppression using GnRH analogs. Long-acting GnRH analogs are the currently preferred treatment option. An advantage to using a GnRH analog is that the effects can be reversed; pubertal suppression can be discontinued if the individual no longer wishes to transition. Upon discontinuation of therapy, spontaneous pubertal development has been shown to resume. The World Professional Association for Transgender Health (WPATH) Standards of Care (version 8) document also recommends the use of GnRH analogs to suppress endogenous sex hormones in transgender and gender diverse people for whom puberty blocking is indicated.¹³ GnRH can also be used in patients during late puberty to suppress the hypothalamic-pituitary-gonadal axis to allow for lower doses of cross-sex hormones.¹⁴ In addition to use in adolescents, GnRH analog therapy is also used in adults, particularly male-to-female patients.¹⁵

In addition to the approved indications, GnRH agonists such as long-acting leuprolide, have been used for other conditions. The National Comprehensive Cancer Network (NCCN) guidelines address the use of GnRH agonists in a number of guidelines:

- **Adolescent and young adult oncology** (version 2.2024 – July 9, 2023) guidelines note GnRH agonists may be used in (oncology) protocols that are predicted to cause prolonged thrombocytopenia and present a risk for menorrhagia.¹⁶ There are some limited data on GnRH agonists to preserve ovarian function during chemotherapy and some have shown that GnRH agonists may be beneficial for fertility preservation, although the guidelines note further investigation is needed and other fertility preservation modalities should still be pursued.
- **Breast cancer** (version 1.2024 – January 25, 2024) guidelines note that luteinizing hormone-releasing hormone agonists, such as leuprolide, can be used for ovarian suppression.¹⁷ Leuprolide dosing per NCCN includes 3.75 mg to 7.5 mg every 4 weeks or 11.25 mg to 22.5 mg every 12 weeks. The guidelines further note that randomized trials have shown that ovarian suppression with GnRH agonist therapy administered during adjuvant chemotherapy in premenopausal women with breast tumors (regardless of hormone receptor status) may preserve ovarian function and diminish the likelihood of chemotherapy-induced amenorrhea.
- **Head and neck cancer** (version 2.2024 – December 08, 2023) guidelines note that a significant number of advanced salivary gland tumors with distant metastases are androgen receptor-positive (AR+), and therefore, the panel recommends patients with tumors that are AR+ receive androgen receptor therapy (i.e., leuprolide, bicalutamide).¹⁸
- **Ovarian cancer including fallopian tube cancer and primary peritoneal cancer** (version 1.2024 – January 17, 2024) guidelines recommend leuprolide as a hormonal therapy option in various settings (e.g., primary therapy, adjuvant therapy, recurrence).¹⁹
- **Uterine neoplasm** guidelines (version 1.2024 – September 20, 2023) notes that GnRH analogs are included as a category 2B option for endometrial stroma sarcoma, adenosarcoma without sarcomatous overgrowth, and estrogen receptor-progesterone receptor positive uterine sarcomas.^{20,23}

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Lupaneta Pack and Lupron Depot. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Lupaneta Pack and Lupron-Depot as well as the monitoring required for adverse events and long-term efficacy, approval for some of the conditions requires Lupaneta Pack or Lupron-Depot to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Lupaneta Pack or Lupron Depot is recommended in those who meet one of the following criteria:

FDA-Approved Indications

22. **Endometriosis.** Approve Lupron Depot (3.75 mg or 11.25 mg) or Lupaneta Pack for 1 year if the patient has tried ONE of the following, unless contraindicated (A, B, or C):
- A) A contraceptive (e.g., combination oral contraceptives, levonorgestrel-releasing intrauterine systems [e.g., Mirena, Liletta]), OR
 - B) An oral progesterone (e.g., norethindrone tablets), OR

02/21/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

C) A depo-medroxyprogesterone injection.

Note: An exception to the requirement for a trial of the above therapies can be made if the patient has previously used a gonadotropin-releasing hormone [GnRH] agonist (e.g., Lupron Depot) or antagonist (e.g., Orilissa).

23. Prostate Cancer. Approve Lupron Depot 7.5 mg, 22.5 mg, 30 mg, or 45 mg for 1 year if prescribed by or in consultation with an oncologist.

24. Uterine Leiomyomata (fibroids). Approve Lupron Depot 3.75 mg or 11.25 mg for 3 months.

Other Uses with Supportive Evidence

25. Abnormal Uterine Bleeding. Approve Lupron Depot 3.75 mg or 11.25 mg for 6 months.

26. Breast Cancer. Approve Lupron Depot 3.75 mg, 7.5mg, 11.25 mg, or 22.5 mg for 1 year if prescribed by or in consultation with an oncologist.

27. Gender Dysphoric/Gender-Incongruent Person; Person Undergoing Gender Reassignment (Female-To-Male [FTM] or Male-To-Female [MTF]). Approve Lupron Depot for 1 year if prescribed by or in consultation with an endocrinologist or a physician who specializes in the treatment of transgender patients.

28. Head and Neck Cancer – Salivary Gland Tumors. Approve Lupron Depot 3.75 mg, 7.5 mg, 11.25mg, or 22.5 mg for 1 year if the patient meets ALL of the following criteria (A, B, and C):

A) Patient has recurrent, unresectable, or metastatic disease; AND

B) Patient has androgen receptor-positive disease; AND

C) The medication is prescribed by or in consultation with an oncologist.

29. Ovarian Cancer, including Fallopian Tube Cancer and Primary Peritoneal Cancer. Approve Lupron Depot 3.75 mg, 7.5 mg, 11.25 mg, or 22.5 mg for 1 year if prescribed by or in consultation with an oncologist.

30. Premenstrual Disorders, including Premenstrual Syndrome and Premenstrual Dysphoric Disorder. Approve the 3.75 mg or 11.25 mg for 1 year if the patient meets ALL of the following criteria (A, B, and C):

A) Patient is ≥ 18 years of age; AND

B) According to the prescriber, the patient has severe, refractory premenstrual symptoms; AND

C) Patient has tried one of the following therapies (i or ii):

i. A selective serotonin reuptake inhibitor (SSRI); OR

Note: Examples of SSRI include citalopram, escitalopram, fluoxetine, fluvoxamine, paroxetine, sertraline.

ii. A combined oral contraceptive.

31. Preservation of Ovarian Function/Fertility in Patients Undergoing Chemotherapy. Approve Lupron Depot 3.75 mg or 11.25 mg for 1 year if prescribed by or in consultation with an oncologist.

32. Prophylaxis or Treatment of Uterine Bleeding or Menstrual Suppression in Patients with Hematologic Malignancy, or Undergoing Cancer Treatment, or Prior to Bone Marrow/Stem Cell Transplantation (BMT/SCT). Approve Lupron Depot 3.75 mg or 11.25 mg for 1 year if prescribed by or in consultation with an oncologist.

- 33. Uterine Cancer.** Approve Lupron Depot 7.5 mg, 22.5 mg, 30 mg, or 45 mg for 1 year if prescribed by or in consultation with an oncologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Lupron Depot and Lupaneta Pack is not recommended in the following situations:

- 22. Menstrual Migraine.** A review article notes that GnRH analogs are effective in eliminating menstrual migraines, but their use is limited due to the significant adverse effects of estrogen deficiency, including severe vasomotor symptoms, sleep disruption, and a marked reduction in bone density.^{21,22}
- 23. Polycystic Ovarian Syndrome (PCOS).** Review articles do not recommend GnRH agonists as a treatment modality for this diagnosis.^{24,25} Additionally, the International Evidence-based Guideline for the Assessment and Management of Polycystic Ovary Syndrome (2018) only mentions GnRH products as they relate to infertility and assisted reproductive technology procedures.²⁶
- 24.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Gonadotropin-Releasing Hormone Antagonists – Myfembree Prior Authorization Policy

- Myfembree® (relugolix, estradiol, and norethindrone acetate tablets – Sumitomo Pharma)

REVIEW DATE: 04/19/2024

OVERVIEW

Myfembree, an oral gonadotropin-releasing hormone (GnRH) receptor antagonist with added estrogen and progestin therapy, is indicated for the following uses:¹

- Management of heavy menstrual bleeding associated with **uterine leiomyomas (fibroids)** in premenopausal women.
- Management of moderate to severe pain associated with **endometriosis** in premenopausal women.

Limitation of Use. Use should be limited to 24 months due to the risk of continued bone loss which may not be reversible.¹

Disease Overview

Uterine fibroids (leiomyomas) are benign tumors. They are the most frequent gynecologic benign disease.² Fibroids can be asymptomatic or cause symptoms; symptoms generally present as abnormal (heavy) uterine bleeding or pelvic pain/pressure. Heavy menstrual bleeding can cause associated problems, such as iron deficiency anemia. The actual prevalence of uterine fibroids is difficult to ascertain since many patients are asymptomatic, but it is estimated that fibroids can be detected in up to 80% of women by 50 years of age.³

Endometriosis is a condition where the tissues similar to the lining of the uterus (or endometrium) migrate outside of the womb to other body sites.^{4,5} The migrated tissues are generally found in the pelvic cavity (e.g., peritoneum, uterosacral ligaments, rectal-vaginal septum, or any spaces between the bladder, uterus, vagina, and rectum) and can attach to any of the female reproductive organs (e.g., ovaries, fallopian tubes). The migrated tissue is less commonly found outside the pelvic cavity or on the intestines, colon, appendix or rectum. Endometriosis impacts up to 10% of patients of reproductive age in the US.⁵

Guidelines

Abnormal Uterine Bleeding/Uterine Leiomyomata (Fibroids)

Myfembree is addressed in the American College of Obstetrician and Gynecologists (ACOG) guidelines on the management of symptomatic uterine leiomyomas (2021) as a medication under clinical study (prior to FDA approval).⁶ Medical treatment options for uterine leiomyomas include agents that address only bleeding symptoms, such as GnRH antagonists, levonorgestrel-releasing intrauterine devices, contraceptive steroids, and tranexamic acid. Agents that reduce both bleeding and leiomyoma size include GnRH agonists and selective progesterone receptor modulators (SPRMs). SPRMs are not approved in the US for the treatment of uterine leiomyomas. An oral GnRH antagonist, such as Oriahnn or Myfembree, can be considered for the treatment of abnormal uterine bleeding related to leiomyomas for up to 2 years. The hormonal add-back therapy is indicated to offset the hypoestrogenic effects of the product.

Endometriosis

According to the ACOG practice bulletin on the management of endometriosis (2010, reaffirmed 2018), empiric therapy with a 3-month course of a GnRH agonist is appropriate after an appropriate pretreatment

04/19/2024

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

evaluation (to exclude other causes of chronic pelvic pain) and failure of initial treatment with oral contraceptives and nonsteroidal anti-inflammatory drugs (NSAIDs).⁷

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Myfembree. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Myfembree as well as the monitoring required for adverse events and long-term efficacy, approval for certain diagnoses requires Myfembree to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Myfembree is recommended in those who meet one of the following criteria:

FDA-Approved Indications

2. **Uterine Fibroids (Leiomyomas).** Approve for up to 24 months if the patient meets ALL of the following (A, B, C, D, E, F, and G):

Note: Approve for **up to** 24 months. For example, a patient who has already received 6 months of treatment with Myfembree should be approved for a duration of 18 months.

- A) Patient is ≥ 18 years of age; AND
- B) Patient is PREmenopausal (before menopause); AND
- C) Patient is experiencing heavy menstrual bleeding associated with the uterine fibroids; AND
- D) Uterine fibroids have been confirmed by a pelvic ultrasound, including transvaginal ultrasonography or sonohysterography; hysteroscopy; or magnetic resonance imaging; AND
- E) Patient has tried at least one other therapy for the medical management of heavy menstrual bleeding; AND
Note: Examples of therapy for the medical management of heavy menstrual bleeding include combination estrogen-progestin contraceptives (oral tablets, vaginal ring, transdermal patch), levonorgestrel-releasing intrauterine systems (e.g., Mirena, Liletta), oral progesterone (e.g., medroxyprogesterone acetate), depo-medroxyprogesterone injection, tranexamic acid tablets.
- F) Patient has not previously received a continuous regimen of 24 months or longer of therapy with Myfembree or Oriahnn; AND
- G) The medication is prescribed by or in consultation with an obstetrician-gynecologist or a health care practitioner who specializes in the treatment of women's health.

3. **Endometriosis.** Approve for up to 24 months if the patient meets ALL of the following criteria (A, B, and C):

Note: Approve for **up to** 24 months. For example, a patient who has already received 6 months of treatment with Myfembree should be approved for a duration of 18 months.

- A) Patient is ≥ 18 years of age; AND
- B) Patient is PREmenopausal (before menopause); AND
- C) Patient has previously tried ONE of the following, unless contraindicated (i or ii):

Note: An exception to this requirement can be made if the patient has previously used a gonadotropin-releasing hormone agonist (e.g., Lupron Depot [leuprolide depot injection]) or Orilissa (elagolix tablets).

- i. A contraceptive (e.g., combination oral contraceptives, levonorgestrel-releasing intrauterine systems [e.g., Mirena {levonorgestrel intrauterine system}, Liletta {levonorgestrel intrauterine system}], depo-medroxyprogesterone injection); OR
- ii. An oral progesterone (e.g., norethindrone tablets).

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Myfembree is not recommended in the following situations:

- 98. Heavy Menstrual Bleeding not associated with Uterine Fibroids.** Myfembree has shown efficacy in reducing heavy menstrual bleeding only in women with uterine fibroids.¹
- 99.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Gonadotropin-Releasing Hormone Antagonists – Oriahnn Prior Authorization Policy

- Oriahnn™ (elagolix, estradiol, and norethindrone acetate capsules; elagolix capsules – AbbVie)

REVIEW DATE: 04/19/2024

OVERVIEW

Oriahnn, an oral gonadotropin-releasing hormone (GnRH) receptor antagonist with added estrogen and progestin therapy, is indicated for the **management of heavy menstrual bleeding associated with uterine leiomyomas (fibroids) in premenopausal women.**¹ Limitation of Use: Use should be limited to 24 months due to the risk of continued bone loss which may not be reversible.¹

Disease Overview

Uterine fibroids (leiomyomas) are benign tumors. They are the most frequent gynecologic benign disease.² Fibroids can be asymptomatic or cause symptoms; symptoms generally present as abnormal (heavy) uterine bleeding or pelvic pain/pressure. Heavy menstrual bleeding can cause associated problems, such as iron deficiency anemia. The actual prevalence of uterine fibroids is difficult to ascertain since many patients are asymptomatic, but it is estimated that fibroids can be detected in up to 80% of women by 50 years of age.³

Guidelines

Oriahnn is addressed in the American College of Obstetrician and Gynecologists guidelines on the management of symptomatic uterine leiomyomas (2021).⁴ Medical treatment options for uterine leiomyomas include agents that address only bleeding symptoms, such as GnRH antagonists, levonorgestrel-releasing intrauterine devices, contraceptive steroids, and tranexamic acid. Agents that reduce both bleeding and leiomyoma size include GnRH agonists and selective progesterone receptor modulators (SPRMs). SPRMs are not approved in the U.S. for the treatment of uterine leiomyomas. An oral GnRH antagonist, such as Oriahnn or Myfembree, can be considered for the treatment of abnormal uterine bleeding related to leiomyomas for up to 2 years. The hormonal add-back therapy is indicated to offset the hypoestrogenic effects of the product.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Oriahnn. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Oriahnn as well as the monitoring required for adverse events and long-term efficacy, approval requires Oriahnn to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Oriahnn is recommended in those who meet the following criteria:

FDA-Approved Indication

- 4. Uterine Fibroids (Leiomyomas).** Approve for up to 24 months if the patient meets ALL of the following (A, B, C, D, E, F, and G):

Note: Approve for **up to** 24 months. For example, a patient who has already received 6 months of treatment with Oriahnn should be approved for a duration of 18 months.

A) Patient is ≥ 18 years of age; AND

B) Patient is PREmenopausal (before menopause); AND

C) Patient is experiencing heavy menstrual bleeding associated with the uterine fibroids; AND

D) Uterine fibroids have been confirmed by a pelvic ultrasound, including transvaginal ultrasonography or sonohysterography; hysteroscopy; or magnetic resonance imaging; AND

E) Patient has tried at least one other therapy for the medical management of heavy menstrual bleeding; AND

Note: Examples of therapy for the medical management of heavy menstrual bleeding includes: combination estrogen-progestin contraceptives (oral tablets, vaginal ring, transdermal patch), levonorgestrel-releasing intrauterine systems [e.g. Mirena, Liletta], oral progesterone (e.g., medroxyprogesterone acetate), depo-medroxyprogesterone injection, tranexamic acid tablets.

F) Patient has **not** previously received a continuous regimen of 24 months or longer of therapy with Oriahnn or Myfembree; AND

G) The medication is prescribed by or in consultation with an obstetrician-gynecologist or a health care practitioner who specializes in the treatment of women's health.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Oriahnn is not recommended in the following situations:

- 100. Heavy Menstrual Bleeding not associated with Uterine Fibroids.**

Oriahnn has been shown to be effective in reducing heavy menstrual bleeding only in women with uterine fibroids.¹

- 101.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Gonadotropin-Releasing Hormone Antagonists – Orilissa Prior Authorization Policy

- Orilissa™ (elagolix tablets – AbbVie)

REVIEW DATE: 04/19/2024

OVERVIEW

Orilissa, an oral gonadotropin-releasing hormone (GnRH) receptor antagonist, is indicated for the management of moderate to severe pain associated with **endometriosis**.¹ Limitation of Use. Limit the duration of use based on the dose and coexisting condition.

The recommended dosage is 150 mg once daily (QD) for up to 24 months (no coexisting conditions) or 200 mg twice daily (BID) for up to 6 months (in patients with coexisting dyspareunia). In patients with moderate hepatic impairment (Child-Pugh Class B), the recommended dosage is 150 mg QD for up to 6 months and the use of 200 mg BID is not recommended. Orilissa is contraindicated in patients with severe hepatic impairment. Duration of therapy is limited due to the anti-estrogenic effects of the medication which include a decrease in bone mineral density.

Disease Overview

Endometriosis is a condition where the tissues similar to the lining of the uterus (or endometrium) migrate outside of the womb to other body sites.^{2,3} The migrated tissues are generally found in the pelvic cavity (e.g., peritoneum, uterosacral ligaments, rectal-vaginal septum, or any spaces between the bladder, uterus, vagina, and rectum) and can attach to any of the female reproductive organs (e.g., ovaries, fallopian tubes). The migrated tissue is less commonly found outside the pelvic cavity or on the intestines, colon, appendix or rectum. Endometriosis impacts up to 10% of patients of reproductive age in the US.³

Guidelines

According to the American College of Obstetricians and Gynecologists practice bulletin on the management of endometriosis (2010, reaffirmed 2018), after an appropriate pretreatment evaluation (to exclude other causes of chronic pelvic pain) and failure of initial treatment with oral contraceptives and nonsteroidal anti-inflammatory drugs (NSAIDs), empiric therapy with a 3-month course of a GnRH agonist is appropriate.²

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Orilissa. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days.

Automation: When available, the ICD-10 codes for endometriosis (N80 through N80.9) **AND** a prior therapy in the last 180 days which includes any one of the following: contraceptives (STCs 0248, 9654, and 9495), intrauterine devices (STC 4730), oral progestins (STC 0246 RT 01), depo-medroxyprogesterone injections (STC 4139), GnRH agonists (STC 8253, STC E851, STC 8254 STR 0190 RT 27), Myfembree, or Orilissa will be used to allow approval of the requested medication.

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Orilissa is recommended in those who meet the following criteria:

FDA-Approved Indication

- 42. Endometriosis.** Approve for 6 months if the patient meets ONE of the following (A or B):
- 17. Initial Therapy.** Approve if the patient has tried ONE of the following, unless contraindicated (i or ii):
- Note: An exception to the requirement for a trial of the below therapies can be made if the patient had previously used a gonadotropin-releasing hormone agonist (e.g., Lupron Depot [leuprolide depot injection]) or Myfembree (relugolix, estradiol, norethindrone tablets) for endometriosis.
- i.** A contraceptive (e.g., combination oral contraceptives, levonorgestrel-releasing intrauterine systems [e.g., Mirena {levonorgestrel intrauterine system}, Liletta {levonorgestrel intrauterine system}], a depo-medroxyprogesterone injection); OR
- ii.** An oral progesterone (e.g., norethindrone tablets); OR
- 18. Patient is Currently Receiving Orilissa.** Approve.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Orilissa is not recommended in the following situations:

- 25.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Gout – Krystexxa Prior Authorization Policy

- Krystexxa® (pegloticase intravenous infusion – Horizon)

REVIEW DATE: 05/15/2024

OVERVIEW

Krystexxa, a PEGylated uric acid specific enzyme, is indicated for treatment of **chronic gout refractory to conventional therapy**, in adult patients.¹ Krystexxa should be co-administered with methotrexate to increase effectiveness, prevent the formation of antibodies, and reduce infusion reactions. It is recommended that patients discontinue oral urate-lowering medications while on Krystexxa therapy due to the potential blunting of the rise of serum uric acid levels with concomitant use. Krystexxa has a Boxed Warning due to concerns for anaphylaxis and infusion reactions, and glucose-6-phosphate dehydrogenase (G6PD) deficiency associated hemolysis and methemoglobinemia.

Krystexxa is specifically labeled for use with methotrexate; however, data are also available to support concomitant use of Krystexxa with azathioprine, leflunomide, or mycophenolate mofetil.⁴⁻⁶

Disease Overview

Gout is a form of inflammatory arthritis and results from a metabolic disorder called hyperuricemia caused by an overproduction or underexcretion of uric acid; however, asymptomatic patients with elevated uric acid levels do not have gout and do not require treatment.^{2,3} Excessive amounts of uric acid in the blood lead to deposits of crystals in the joints and connective tissues and may cause excruciating pain. Lumps of urate crystals (tophi) may develop in soft tissues such as the elbow, ear, or distal finger joints. Some patients fail to normalize serum uric acid and have inadequate control of the signs and symptoms of gout with maximum medically appropriate doses or have a contraindication to urate-lowering therapies. Treatment-failure should be differentiated as those who are under-treated for gout or are non-compliant with gout therapy. Those with treatment-failure gout generally have a high prevalence of tophi, frequent and disabling gout flares, deforming arthropathy, diminished quality of life, and disability.

Guidelines

The American College of Rheumatology provides guidelines (2020) for the management of gout. Allopurinol is the preferred first-line urate-lowering therapy, including patients with moderate to severe gout.³ Febuxostat and probenecid are conditionally recommended as alternative first-line therapies for specific patient populations. Titration of urate-lowering therapy should be guided by serum uric acid concentrations, with a target of < 6 mg/dL. In patients with refractory disease, effective therapeutic options include combination therapy with a xanthine oxidase inhibitor (e.g., allopurinol or febuxostat) and a uricosuric agent (e.g., probenecid, fenofibrate, or losartan). Krystexxa is not recommended as first-line therapy, however it is appropriate in patients with severe gout disease burden and refractoriness to, or intolerance of, appropriately dosed oral urate-lowering therapies.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Krystexxa. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Krystexxa as well as the monitoring required for adverse events and long-term efficacy, approval

05/15/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

requires Krystexxa to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Krystexxa is recommended in those who meet the following criteria:

FDA-Approved Indication

1. Gout, Chronic. Approve for the duration noted below if the patient meets ONE of the following (A or B):

A) Initial Therapy. Approve for 6 months if the patient meets ALL of the following (i, ii, iii, iv, v, and vi):

i. Patient meets ONE of the following (a or b):

a) Patient has at least one tophus; OR

b) Patient has a of 2 previous gout flares in the past year (prior to the current flare); AND

ii. Patient meets ONE of the following (a or b):

a) Patient had an inadequate response, defined as serum uric acid level that remained > 6 mg/dL following a 3-month trial of a xanthine oxidase inhibitor; OR

Note: Examples of xanthine oxidase inhibitors include allopurinol, febuxostat.

b) Patient has a contraindication or has had an intolerance to a trial of allopurinol, as determined by the prescriber; AND

iii. Patient meets ONE of the following (a or b):

a) Patient had an inadequate response, defined as serum uric acid level that remained > 6 mg/dL following a 3-month trial of a uricosuric agent; OR

Note: Examples of uricosuric agents include probenecid, fenofibrate, losartan.

b) According to the prescriber, the patient has renal insufficiency (e.g., decreased glomerular filtration rate); AND

iv. Krystexxa will be used in combination with ONE of the following (a, b, c or d):

a) Methotrexate; OR

b) Leflunomide; OR

c) Mycophenolate mofetil; OR

d) Azathioprine; AND

v. Krystexxa will not be used in combination with another uric acid lowering drug; AND

Note: Examples of uric acid lower drugs include allopurinol, febuxostat, probenecid.

vi. Krystexxa is prescribed by or in consultation with a rheumatologist or a nephrologist.

B) Patient is Currently Receiving Krystexxa. Approve for 1 year if the patient meets ALL of the following (i, ii, iii, iv, and v):

i. Patient is continuing therapy with Krystexxa to maintain response/remission; AND

ii. Patient has responded to therapy with evidence of serum uric acid level < 6 mg/dL with continued Krystexxa treatments; AND

iii. Krystexxa is being used in combination with ONE of the following (a, b, c or d):

a) Methotrexate; OR

b) Leflunomide; OR

c) Mycophenolate mofetil; OR

d) Azathioprine; AND

iv. Krystexxa is not being used in combination with another uric acid lowering drug.

Note: Examples of uric lower drugs include allopurinol, febuxostat, probenecid.

v. Krystexxa is prescribed by or in consultation with a rheumatologist or a nephrologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Krystexxa is not recommended in the following situations:

102. **Known Glucose-6-Phosphate Dehydrogenase (G6PD) Deficiency.** Because of risks of hemolysis and methemoglobinemia, Krystexxa is contraindicated in G6PD deficiency.¹ Patients at increased risk of this deficiency (e.g., those of African or Mediterranean ancestry) should be screened prior to initiation of therapy.
103. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

REVIEW DATE: 04/03/2024

OVERVIEW

Indications for somatropin vary among these products. Somatropin is indicated for the following uses:

- **Growth hormone deficiency (GHD) or failure**, treatment of pediatric patients, due to an inadequate secretion of endogenous growth hormone.¹⁻⁷
- **Non-growth hormone deficient short stature (idiopathic short stature)**, treatment, defined by height standard deviation score (SDS) ≤ -2.25 , and associated with growth rates unlikely to permit attainment of adult height in the normal range.^{1-4,6,7}
- **Adults with GHD** for replacement of endogenous growth hormone.¹⁻⁷
- **Children with chronic kidney disease**, treatment of growth failure, up to the time of kidney transplantation.⁴
- **Noonan syndrome**, treatment of patients with short stature.³
- **Prader Willi syndrome**, treatment of patients with growth failure or short stature.^{1,3,7}
- **Short stature homeobox-containing gene (SHOX) deficiency**, treatment of short stature or growth failure in children.^{2,6}
- **Small for gestational age (SGA)**, treatment of growth failure or short stature in patients with no catch-up growth by age 2^{1,7} to 4 years^{2,3,6}
- **Turner syndrome**, treatment of short stature.^{1-4,6,7}
- **Short bowel syndrome**, treatment, in adults receiving specialized nutritional support.⁸
- **Human immunodeficiency virus (HIV)-infected patients with wasting or cachexia**, treatment, to increase lean body mass and body weight, and improve physical endurance.⁹

Growth Hormone Deficiency (GHD) in Children and Adolescents

Somatropin is indicated for the treatment of growth failure in children due to an inadequate secretion of endogenous growth hormone.¹⁻⁷ In these children with GHD, somatropin is effective for increasing final adult height.³¹ Somatropin therapy is recommended to normalize adult height and avoid extreme shortness in children and adolescents with GHD.³¹ Cranial radiation often causes hypopituitarism, and GHD is a frequent pituitary abnormality seen in children and adults who have undergone cranial radiation.¹⁷ Children who have undergone total body irradiation in preparation for hematopoietic stem cell transplant commonly have GHD and an impaired growth rate; these patients can be treated successfully with growth hormone. Somatropin therapy improves the final height of young children after total body irradiation.¹¹

Congenital Hypopituitarism

04/03/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Somatropin is used in infants and young children with congenital hypopituitarism, that manifests in infancy with hypoglycemia, microgenitalia, hyperbilirubinemia, and multiple anterior pituitary hormone deficiencies.³¹ The Pediatric Endocrine Society guidelines suggest that GHD due to congenital hypopituitarism be diagnosed without formal growth hormone provocative testing in a newborn with hypoglycemia who does not attain a serum growth hormone concentration > 5 mcg/L (> 5 ng/mL) and has deficiency of at least one additional pituitary hormone and/or the classical imaging triad (ectopic posterior pituitary and pituitary hypoplasia with abnormal stalk).³¹

Non-Growth Hormone Deficient Short Stature (Idiopathic Short Stature) in Children or Adolescents

Somatropin is indicated for the long-term treatment of idiopathic short stature (non-growth hormone deficient short stature) which is defined by a height standard deviation score (SDS) ≤ -2.25 , and associated with growth rates that are unlikely to permit attainment of adult height in the normal range.^{1-4,6,7} The predicted adult heights of these children are < 160 cm (63 inches) for men and < 150 cm (59 inches) in women.³¹ The Pediatric Endocrine Society guidelines (2016) recommend that the decision to treat idiopathic short stature with somatropin be made on a case-by-case basis after assessing physical and psychological burdens, and discussion of risks and benefits.³¹ They recommend against the routine use of somatropin in every child with height SDS ≤ -2.25 . In one consensus statement on children with idiopathic short stature from the Growth Hormone Research Society, the Lawson Wilkins Pediatric Endocrine Society, and the European Society for Paediatric Endocrinology Workshop (2008), it was felt that the optimal age for initiating treatment is 5 years to early puberty.¹²

The initial 6-month trial of somatropin is to establish that the child's condition responds to somatropin therapy. Authorization for continued therapy should be based on an adequate clinical response defined as an annualized growth rate that doubles in comparison to the previous year.¹⁴ Children who show a striking increase in growth velocity during the first 6 to 12 months of somatropin therapy are most likely to benefit from long-term therapy, and therapy should be discontinued if there is no significant increase in growth rate during the first year. Children who have a significant increase in growth rate after the first 6-month trial and the next 12 months should then be reviewed annually for growth rate, closure of the epiphyses, and/or attainment of mid-parental height.

Growth Hormone Deficiency (GHD) in Adults or Transition Adolescents

Somatropin is indicated for the replacement of endogenous growth hormone in adults with GHD, which may present in adults or children as GHD (isolated GHD) or in addition to other pituitary hormone deficiencies (gonadotropin, adrenocorticotrophic hormone, and/or thyroid-stimulating hormone deficiencies).¹⁵ Patients with other anterior pituitary hormone deficiencies are likely to have GHD. In adults, the diagnosis of GHD usually is made in patients with signs and symptoms of hypothalamic-pituitary disease (endocrine, structural, and/or genetic causes); those who have received cranial irradiation or tumor treatment; or those with traumatic brain injury or subarachnoid hemorrhage.^{15,16} Onset may be in adulthood or childhood. In childhood, the goal of somatropin therapy is primarily for statural growth. When final adult height is attained, somatropin therapy is no longer required for statural growth. Transition is used to describe the period in adolescence after growth is completed and the need for continued replacement into adulthood is assessed. Ongoing GHD is most likely in patients with multiple pituitary hormone deficits, with or without structural pituitary or peripituitary disease, and/or a history of cranial radiation therapy. Confirmatory growth hormone stimulation testing may not be required in patients, such as with congenital/genetic GHD or multiple pituitary hormone deficiencies. When persistent GHD is documented after completion of adult height, somatropin therapy should be continued to attain full skeletal and muscle maturation during the transition period from childhood to adulthood.¹⁵ In adults with GHD, somatropin replacement therapy improves abnormalities in substrate metabolism, body composition, and physical and psychosocial function.^{15,16}

Growth hormone is not approved by the FDA for the treatment of other conditions in adults who may have a low growth hormone response to growth hormone provocative testing (such as obesity, aging, or depression) or to improve athletic performance.^{17,18}

Growth Hormone Stimulation Tests (Adults or Transition Adolescents)

The insulin tolerance test is the gold standard growth hormone stimulation test⁵³ but is contraindicated in patients with ischemic heart disease or seizure disorders or in elderly or pregnant patients.^{15,16,27} The glucagon stimulation test and the macimorelin test could be considered as alternatives.⁵³ The response to all growth hormone stimulation tests show intra-individual variability, and the growth hormone cutoff points vary with the test used. Otherwise healthy obese persons have blunted growth hormone responses to various tests.³⁰ There is no information on the effects of increased body mass index (BMI) or central adiposity on the insulin tolerance test. When Geref (growth hormone releasing hormone) was available [discontinued in the US in 2008], Geref plus arginine was considered the best alternative to the insulin tolerance test in adults.

Macrilen (macimorelin oral solution) is the most recently approved test for the diagnosis of adult GHD. Patients in the pivotal trial were 18 to 66 years of age and the BMI ranged from 16 to 40 kg/m².²⁹ Safety and diagnostic performance have not been established in patients with BMI > 40 kg/m². Clinical studies established that a maximally stimulated serum growth hormone level of < 2.8 ng/mL (i.e., at the 30, 45, 60, and 90 minute time points) after Macrilen administration confirms the presence of adult GHD.

Arginine and levodopa testing have not been systematically evaluated and validated, and because they have a low sensitivity and specificity in adults and transition patients, it is not recommended to utilize these tests in this population.⁵³ Additionally, the clonidine, levodopa, and arginine alone tests are generally not recommended because very low growth hormone cutoff points are required to achieve adequate specificity.²⁷

Adults with childhood onset GHD may have alterations in body composition, bone mineral density, and lipid metabolism that are alleviated by treatment with somatropin.^{15,31} However, some children with a diagnosis of GHD have a normal somatotrophic axis when retested in late adolescence.^{31,52} Re-evaluation of the somatotrophic axis in children diagnosed with GHD is required during the transition period. The transition period is the time from late puberty to establishment of adult muscle and bone composition, and encompasses attainment of adult height.³¹ Re-evaluation of the somatotrophic axis is most conveniently done when growth has slowed to the point where pediatric somatropin dosing will be discontinued (i.e., the growth velocity is < 2 to 2.5 cm/year). Recommendations for transitional care after childhood somatropin treatment from the Pediatric Endocrine Society guidelines³¹ are as follows: Patients with multiple (≥ 3) pituitary hormone deficiencies regardless of etiology, or GHD with a documented causal genetic mutation or specific pituitary/hypothalamic structural defect (except ectopic posterior pituitary) be diagnosed with persistent GHD. These guidelines recommend re-evaluation of the somatotrophic axis for persistent GHD in persons with 1) GHD and deficiency of only one additional pituitary hormone, 2) idiopathic isolated GHD, 3) idiopathic isolated GHD with or without a small pituitary/ectopic posterior pituitary, and 4) in patients after irradiation. Testing can be done after a trial of at least 1 month off somatropin treatment. The guidelines also recommend growth hormone provocative testing to evaluate the function of the somatotrophic axis in the transition period if indicated by a low insulin-like growth factor (IGF)-1 level. Persons with idiopathic isolated GHD will very likely test sufficient with growth hormone provocative testing. To continue growth hormone therapy in adulthood, retesting for GHD with growth hormone stimulation test(s) is recommended in most transition patients and at least 1 month after discontinuation of pediatric growth hormone therapy.⁵³ Retesting is not required in transition patients with evidence of

panhypopituitarism (≥ 3 pituitary hormone deficiencies) and low serum IGF-1 levels, patients with genetic defects, and patients with hypothalamic-pituitary structural brain defects.

Adult GHD can be predicted with $> 90\%$ accuracy by the presence of three or four pituitary hormone deficiencies in addition to serum IGF-1 concentration that is less than the 2.5 percentile or < -2 SDS.^{15,16} This is in the absence of conditions that lower IGF-1. Patients with ≥ 3 pituitary hormone deficiencies and an IGF-1 level below the reference range do not need a growth hormone stimulation test.¹⁶ Because of the nature of the cause of GHD in children with structural lesions with multiple hormone deficiencies and those with proven genetic causes, provocative testing in these adults is not necessary.

Chronic Kidney Disease in Children or Adolescents

Somatropin is indicated for the treatment of growth failure in children with chronic kidney disease up to the time of kidney transplantation and is effective for increasing the rate of growth.⁴ Somatropin therapy has increased final adult height in these patients.¹⁹ An adequate growth response can be assumed if height velocity during the first year of growth hormone treatment is greater than 2 cm per year over baseline.²⁰ This increase is supported by outcomes of controlled trials specific to patients with chronic kidney disease. Guidelines recommend that persistent growth failure (defined as height below the third percentile and height velocity below the 25th percentile beyond a period of 3 months in infants or 6 months in children and adolescents), be an indication for growth hormone therapy once other potentially treatable risk factors for growth failure have been adequately addressed.²⁰ Growth hormone therapy can be initiated 1 year after transplantation if spontaneous catch-up growth does not occur and steroid-free immunosuppression is not a feasible option.

Noonan Syndrome and Short Stature in Children or Adolescents

Somatropin is indicated for the treatment of children with short stature associated with Noonan syndrome.^{3,21} Not all patients with Noonan syndrome have short stature; some will achieve a normal adult height without treatment. The younger the age at start of therapy, the larger the change in height SDS.

Prader-Willi Syndrome

Somatropin is indicated for the treatment of pediatric patients who have growth failure due to Prader-Willi syndrome.^{1,3,7} Somatropin therapy in children increases linear growth velocity, improves body composition (i.e., decreases the percentage body fat, increases or stabilizes lean body mass), increases bone mineral density, improves physical strength and agility, and improves final adult height.²² After final height is attained, there may be potential benefits of somatropin on body composition, peak bone mass, cognition, and quality of life in adults.²² Somatropin is contraindicated in patients with Prader-Willi syndrome who are severely obese or have severe respiratory impairment.^{1,3,7} Confirmation of Prader-Willi requires molecular genetic testing for the identification of Prader-Willi genetic subtypes.⁵⁴

Short Stature Homeobox-Containing Gene (SHOX) Deficiency in Children or Adolescents

Somatropin is indicated for the treatment of short stature or growth failure in children with SHOX deficiency.^{2,6} SHOX deficiency may result from either deletion of one copy of the *SHOX* gene or from mutation within or outside one copy of the *SHOX* gene that impairs the production or function of the SHOX protein. Women with Turner syndrome have only a single copy of the *SHOX* gene because they lack all or part of their second X chromosome.²³ SHOX deficiency is also the primary cause of short stature in most patients with Léri-Weill dyschondrosteosis (syndrome), and *SHOX* mutations and deletions are found in patients with idiopathic short stature. In one study consisting of a 2-year control period and a subsequent extension period to final height, short prepubertal patients with SHOX deficiency received somatropin.²⁴

Children Born Small for Gestational Age (SGA)

Somatropin is indicated for the treatment of growth failure in children born SGA who fail to exhibit catch-up growth by age 2^{1,7} to 4 years.^{2,3,6} SGA is defined as a birth weight and/or birth length that is greater than 2 standard deviation (SD) [about the 3rd percentile] below mean normal values after adjusting for gestational age and sex. The terms SGA and intrauterine growth restriction are used interchangeably in this document. In clinical trials, patients born SGA (including children with Silver-Russell syndrome) without catch-up growth who were 2 to 11 years of age had significant increases in growth when treated with somatropin before puberty.^{1,3} Optimal duration of therapy once catch-up growth has been attained is not known.

Almost all patients with Silver-Russell syndrome are born SGA, and postnatal catch-up growth does not occur in the majority of children.⁴⁴ An expert consensus statement recommends that patients with Silver-Russell syndrome receive treatment with somatropin as soon as possible.⁴⁴ Starting therapy at age 2 to 4 years is adequate for the majority of patients. In some cases, somatropin therapy is started in patients less than 2 years of age who have severe fasting hypoglycemia, severe malnutrition, or severe muscular hypotonia. These experts recommend that somatropin therapy be stopped when height velocity is < 2 cm per year over a 6-month period and when bone age is > 14 years in females or > 17 years in males.

Turner Syndrome

Somatropin is indicated for the treatment of short stature associated with Turner syndrome.^{1-4,6,7} Turner syndrome is a sex chromosome disorder caused by loss of part or all of an X chromosome; the diagnosis is confirmed by karyotype analysis. Growth hormone therapy is used to maximize adult height in these patients; there is no physiological rationale for continuing growth hormone into the transition period after the completion of puberty.²⁵

Short Bowel Syndrome

Somatropin is indicated for the treatment of short bowel syndrome in adults receiving specialized nutritional support.¹¹

Human Immunodeficiency Virus-Associated Wasting or Cachexia

Somatropin is indicated for the treatment of HIV-infected adults with wasting (loss of lean body mass) or cachexia to increase lean body mass and body weight, and improve physical endurance.⁹ Somatropin therapy increases lean body mass, decreases fat mass, and increases physical function in patients with HIV-associated wasting. Studies directly comparing somatropin with other therapies (megestrol, oxandrolone, testosterone, and progressive resistance training) for wasting or cachexia in HIV-infection are lacking.²⁶

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of somatropin. All reviews will be directed to a clinician (i.e., pharmacist) for verification of criteria. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with somatropin as well as the monitoring required for adverse events and long-term efficacy, approval for some indications requires somatropin to be evaluated by a physician who specializes in the condition being treated. Human growth hormone is FDA-approved for treatment of a limited number of conditions. The FDA has not approved the use of human growth hormone as therapy for anti-aging, longevity, cosmetic uses, or performance enhancement. Federal law prohibits the dispensing of human growth hormone for non-approved purposes. A pharmacy's failure to comply with that law could result in significant criminal penalties to the pharmacy and its employees. Accordingly, a pharmacy may decline to dispense prescriptions for human growth hormone when written by physicians or other authorized prescribers who they believe may be involved in or affiliated with the fields of anti-aging, longevity, rejuvenation, cosmetic uses, performance enhancement, or sports medicine.

Documentation: Documentation is required for use of somatropin as noted in the criteria as **[documentation required]**. Documentation may include, but is not limited to, chart notes, prescription claims records, prescription receipts, and/or other information. For patient cases in which documentation is required, if this documentation has been previously received upon a prior coverage review, the documentation requirement is considered to be met.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

I. Coverage of Genotropin, Humatrope, Norditropin, Nutropin AQ, Omnitrope, Saizen, and Zomacton (all listed products except Serostim and Zorbtive) is recommended in those who meet at least ONE of the following criteria:

FDA-Approved Indications

1. **Growth Hormone Deficiency in a Child or Adolescent.** Approve for 1 year if the patient meets ONE of the following (A or B):

A) Initial therapy. Approve if the patient meets at least ONE of the following (i, ii, iii, iv, or v):

i. Patient meets BOTH of the following (a and b):

a) Patient meets at least ONE of the following (1 or 2):

(1) Patient has had two growth hormone stimulation tests performed with any of the following agents: levodopa, insulin-induced hypoglycemia, arginine, clonidine, or glucagon AND the peak growth hormone response to both tests are < 10 ng/mL; OR

(2) Patient meets BOTH of the following (i and ii):

(i) Patient has had at least one growth hormone stimulation test performed with any of the following agents: levodopa, insulin-induced hypoglycemia, arginine, clonidine, or glucagon AND the peak growth hormone response to at least one test is < 10 ng/mL; AND

(ii) Patient has at least one risk factor for growth hormone deficiency; AND

Note: Examples of at least one risk factor for growth hormone deficiency includes: the height for age curve has deviated downward across two major height percentiles [e.g., from above the 25th percentile to below the 10th percentile]; patient's growth rate is less than the expected normal growth rate based on age and gender; patient has low insulin-like growth factor (IGF)-1 and/or IGF binding protein-3 levels; patient has a very low peak growth hormone level on provocative testing as defined by the prescribing physician; patient's growth velocity is less than the 10th percentile for age and gender [height velocity percentile is NOT the same as height-for-age percentile]; patient is status post craniopharyngioma resection; patient has optic nerve hypoplasia; patient has a growth hormone gene deletion.

Note: Some patients will achieve stimulated growth hormone concentrations in the normal range as determined by the testing laboratory and could be reviewed for authorization under non-growth hormone deficiency short stature (idiopathic short stature); AND

b) Patient has been evaluated by an endocrinologist; OR

ii. Patient has undergone brain radiation or tumor resection AND meets BOTH of the following (a and b):

a) Patient meets at least ONE of the following (1 or 2):

- (1) Patient meets BOTH of the following (i and ii):
 - (i) Patient has had one growth hormone stimulation test with any of the following agents: levodopa, insulin-induced hypoglycemia, arginine, clonidine, or glucagon; AND
 - (ii) The peak growth hormone response to at least one test is < 10 ng/mL; OR
 - (2) Patient has a deficiency in at least one other pituitary hormone (i.e., adrenocorticotrophic hormone, thyroid-stimulating hormone, gonadotropin deficiency [luteinizing hormone and/or follicle stimulating hormone deficiency are counted as one deficiency], or prolactin); AND
 - b) Patient has been evaluated by an endocrinologist; OR
 - iii. Patient has congenital hypopituitarism AND meets BOTH of the following (a and b):
 - a) Patient meets at least ONE of the following (1, 2, or 3):
 - (1) Patient meets BOTH of the following (i and ii):
 - (i) Patient has had one growth hormone stimulation test with any of the following agents: levodopa, insulin-induced hypoglycemia, arginine, clonidine, or glucagon; AND
 - (ii) The peak growth hormone response to at least one test is < 10 ng/mL; OR
 - (2) Patient has a deficiency in at least one other pituitary hormone (i.e., adrenocorticotrophic hormone, thyroid-stimulating hormone, gonadotropin deficiency [luteinizing hormone and/or follicle stimulating hormone deficiency are counted as one deficiency], or prolactin); OR
 - (3) Patient has the imaging triad of ectopic posterior pituitary and pituitary hypoplasia with abnormal pituitary stalk; AND
 - b) Patient has been evaluated by an endocrinologist; OR
 - iv. Patient has multiple pituitary hormone deficiencies and meets BOTH of the following (a and b):

Note: Growth hormone deficiency may occur in combination with other pituitary hormone deficiencies and is referred to as hypopituitarism, panhypopituitarism, or multiple pituitary hormone deficiency.

 - a) Patient meets at least ONE of the following (1 or 2):
 - (1) Patient has three or more of the following pituitary hormone deficiencies: somatropin (growth hormone), adrenocorticotrophic hormone, thyroid-stimulating hormone, gonadotropin deficiency (luteinizing hormone and/or follicle stimulating hormone deficiency are counted as one deficiency), and prolactin; OR
 - (2) Patient meets BOTH of the following (i and ii):
 - (i) Patient has had one growth hormone stimulation test with any of the following agents: levodopa, insulin-induced hypoglycemia, arginine, clonidine, or glucagon; AND
 - (ii) The peak growth hormone response to at least one test is < 10 ng/mL; AND
 - b) Patient has been evaluated by an endocrinologist; OR
 - v. Patient has had a hypophysectomy (surgical removal of pituitary gland).
- B) Patient is continuing somatropin therapy (i.e., established on somatropin for ≥ 10 months). Approve if the patient meets at least ONE of the following (i, ii, or iii):
 - i. Patient is < 12 years of age. Patient's height has increased by ≥ 2 cm/year in the most recent year; OR
 - ii. Patient is between ≥ 12 years and < 18 years of age. Patient meets BOTH of the following (a and b):
 - a) Patient's height has increased by ≥ 2 cm/year in the most recent year; AND
 - b) Patient's epiphyses are open; OR
 - iii. Patient is ≥ 18 years of age. Patient meets ALL of the following (a, b, and c):

- a) Patient's height has increased by ≥ 2 cm/year in the most recent year; AND
- b) Patient's epiphyses are open; AND
- c) Patient's mid-parental height has not been attained.

Note: Mid-parental height is the father's height plus the mother's height divided by 2, plus 2.5 inches if male or minus 2.5 inches if female.

Note: Adolescents and young adults with childhood onset growth hormone deficiency who have previously responded to somatropin with increases in height velocity and who have completed linear growth may continue receiving somatropin therapy as a transition adolescent or as an adult. See criteria I.3. (Growth hormone deficiency in an adult or transition adolescent).

2. Non-Growth Hormone Deficient Short Stature (Idiopathic Short Stature) in a Child or Adolescent. Approve for the duration noted if the patient meets at least ONE of the following (A or B):

A) Initial therapy. Approve for 6 months if the patient meets ALL of the following (i, ii, iii, iv, v, and vi):

- i. Patient is ≥ 5 years of age; AND
- ii. Patient's baseline height is ≤ 1.2 percentile or a standard deviation score (SDS) ≤ -2.25 for age and gender; AND
- iii. Patient's growth (height) velocity meets at least ONE of the following (a or b):
 - a) Patient has a growth rate < 4 cm/year; OR
 - b) Patient's growth (height) velocity is less than the 10th percentile for age and gender based on at least 6 months of growth data; AND

Note: Height velocity percentile is NOT the same as height for age percentile.
- iv. Without growth hormone therapy, the patient's predicted adult height is < 160 cm (63 inches) in males or < 150 cm (59 inches) in females; AND
- v. Patient's epiphyses are open; AND
- vi. Patient does not have constitutional delay of growth and puberty.

B) Patient is continuing somatropin therapy. Approve for 1 year if the patient meets at least ONE of the following (i or ii):

- i. Patient has received somatropin for ≥ 6 months and < 10 months. Approve if the patient meets BOTH of the following (a and b):
 - a) Patient is ≥ 5 years of age; AND
 - b) Patient's annualized growth rate has doubled in comparison to the previous year; OR

Note: For example, if the growth velocity was 3 cm/year for the year prior to treatment, then the growth velocity must be at least 3 cm in 6 months (baseline velocity was 1.5 cm/6 months) or for example, the growth velocity was 2 cm/year for the year prior to treatment, then after 6 months of somatropin therapy, the growth velocity must be at least 2 cm in 6 months (1 cm/6 months baseline).
- ii. Patient has received somatropin for ≥ 10 months. Approve if the patient meets at least ONE of the following (a, b, or c):
 - a) Patient is ≥ 5 years and < 12 years of age. Patient's height has increased by ≥ 2 cm/year in the most recent year; OR
 - b) Patient is ≥ 12 years of age and < 18 years of age. Patient meets BOTH of the following (1 and 2):
 - (1) Patient's height has increased by ≥ 2 cm/year in the most recent year; AND
 - (2) Patient's epiphyses are open; OR
 - c) Patient is ≥ 18 years of age. Patient meets ALL of the following (1, 2, and 3):
 - (1) Patient's height has increased by ≥ 2 cm/year in the most recent year; AND
 - (2) Patient's epiphyses are open; AND

(3) Patient's mid-parental height has not been attained.

Note: Mid-parental height is the father's height plus the mother's height divided by 2, plus 2.5 inches if male or minus 2.5 inches if female.

3. Growth Hormone Deficiency in an Adult or Transition Adolescent. Approve for 1 year if the patient meets ALL of the following (A, B, C, and D):

A) The endocrinologist must certify that somatropin is not being prescribed for anti-aging therapy or to enhance athletic ability or for body building; AND

B) Patient must have a diagnosis of growth hormone deficiency that is ONE of the following (i or ii):
[documentation required for all elements]

i. Childhood onset; OR

ii. Adult onset that results from one of the following: growth hormone deficiency alone or multiple hormone deficiencies (hypopituitarism) resulting from pituitary disease, hypothalamic disease, pituitary surgery, cranial radiation therapy, tumor treatment, traumatic brain injury, or subarachnoid hemorrhage; AND

C) Patient meets at least ONE of the following (i, ii, or iii):

i. Patient (adult or transition adolescent) has known perinatal insults OR congenital or genetic defects; **[documentation required]** OR

ii. Patient meets ALL of the following (a, b, and c):

a) Patient (adult onset or transition adolescent) has three or more of the following pituitary hormone deficiencies: Adrenocorticotrophic hormone, thyroid-stimulation hormone, gonadotropin deficiency (luteinizing hormone and/or follicle stimulating hormone deficiency are counted as one deficiency), and prolactin **[documentation required]**; AND

b) The age and gender adjusted serum insulin-like growth factor-1 is below the lower limit of the normal reference range for the reporting laboratory **[documentation required]**; AND

c) Other causes of low serum insulin-like growth factor-1 have been excluded (e.g., malnutrition, prolonged fasting, poorly controlled diabetes mellitus, hypothyroidism, hepatic insufficiency, oral estrogen therapy); OR

iii. Patient meets at least ONE of the following (a or b):

a) Adult. Patient has had a negative response to at least ONE of the following standard growth hormone stimulation tests (1, 2, 3, 4, 5, or 6) **[documentation required for all elements]**:
Note: If the patient has had a previous trial of an arginine test with a peak response of ≤ 0.4 mcg/L, this would meet the criteria for a negative response to a growth hormone stimulation test.

(1) Insulin tolerance test (obtaining at least 3 growth hormone levels in at least a 60 minute timeframe [not including a level at timeframe zero], with adequate hypoglycemia being achieved) with peak response ≤ 5.0 mcg/L; OR

(2) Glucagon stimulation test (obtaining at least 3 growth hormone levels in at least 180 minute timeframe [not including a level at timeframe zero]) with peak response ≤ 3.0 mcg/L AND the patient's body mass index (BMI) is < 25 kg/m²; OR

(3) Glucagon stimulation test (obtaining at least 3 growth hormone levels in at least 180 minute timeframe [not including a level at timeframe zero]) with a peak response ≤ 3.0 mcg/L AND the patient's BMI is ≥ 25 kg/m² and ≤ 30 kg/m² with, according to the prescriber, a high pretest probability of growth hormone deficiency; OR

(4) Glucagon stimulation test (obtaining at least 3 growth hormone levels in at least 180 minute timeframe [not including a level at timeframe zero]) with a peak response ≤ 1.0 mcg/L AND the patient's BMI is ≥ 25 kg/m² and ≤ 30 kg/m² with, according to the prescriber, a low pretest probability of growth hormone deficiency; OR

- (5) Glucagon stimulation test (obtaining at least 3 growth hormone levels in at least 180 minute timeframe [not including a level at timeframe zero]) with peak response ≤ 1.0 mcg/L AND the patient's BMI is $> 30 \text{ kg/m}^2$; OR
- (6) Macrilen (macimorelin oral solution) test (obtaining at least 4 growth hormone levels in at least a 90 minute timeframe [not including a level at timeframe zero]) with peak responses $< 2.8 \text{ ng/mL}$ (2.8 mcg/L) AND the patient's BMI is $\leq 40 \text{ kg/m}^2$.

Note: The following formula can be used to calculate BMI: BMI equals body weight in kg divided by height meters squared (m^2) [i.e., $\text{BMI} = \text{kg/m}^2$]; OR

- b) Transition adolescent. Patient meets BOTH of the following (1 and 2): **[documentation required for all elements]**:

Note: The transition period is the time from late puberty to establishment of adult muscle and bone composition, and encompasses attainment of adult height.

Note: If the patient has had a trial of a Macrilen test with a peak response of $< 2.8 \text{ ng/mL}$ (mcg/L), this would meet the criteria for a negative response to a growth hormone stimulation test.

- (1) Patient has been off somatropin therapy for at least 1 month before retesting with a growth hormone stimulation test; AND
- (2) Patient meets at least ONE of the following responses to growth hormone stimulation testing (i, ii, iii, iv, v or vi):
 - (i) Insulin tolerance test (obtaining at least 3 growth hormone levels in at least a 60 minute timeframe [not including a level at timeframe zero], with adequate hypoglycemia being achieved) with peak response $\leq 5.0 \text{ mcg/L}$; OR
 - (ii) Glucagon stimulation test (obtaining at least 3 growth hormone levels in at least 180 minute timeframe [not including a level at timeframe zero]) with peak response $\leq 3.0 \text{ mcg/L}$ AND the patient's body mass index (BMI) is $< 25 \text{ kg/m}^2$; OR
 - (iii) Glucagon stimulation test (obtaining at least 3 growth hormone levels in at least 180 minute timeframe [not including a level at timeframe zero]) with a peak response of $\leq 3.0 \text{ mcg/L}$ AND the patient's BMI is $\geq 25 \text{ kg/m}^2$ and $\leq 30 \text{ kg/m}^2$ with, according to the prescriber, a high pretest probability of growth hormone deficiency; OR
 - (iv) Glucagon stimulation test (obtaining at least 3 growth hormone levels in at least 180 minute timeframe [not including a level at timeframe zero]) with a peak response $\leq 1.0 \text{ mcg/L}$ AND the patient's BMI is $\geq 25 \text{ kg/m}^2$ and $\leq 30 \text{ kg/m}^2$ with, according to the prescriber, a low pretest probability of growth hormone deficiency; OR
 - (v) Glucagon stimulation test (obtaining at least 3 growth hormone levels in at least 180 minute timeframe [not including a level at timeframe zero]) with peak response $\leq 1.0 \text{ mcg/L}$ AND the patient's BMI is $> 30 \text{ kg/m}^2$; OR
 - (vi) If both the insulin tolerance test AND glucagon stimulation test are contraindicated, the arginine test can be used (obtaining at least 3 growth hormone levels in at least 120 minute timeframe [not including a level at timeframe zero]) with a peak response $\leq 0.4 \text{ mcg/L}$; AND

D) Patient has been evaluated by an endocrinologist.

4. Chronic Kidney Disease in a Child or Adolescent. Approve for 1 year if the patient meets BOTH of the following (A and B):

- A) Patient has or had chronic kidney disease as defined by a glomerular filtration rate < 60 milliliters/minute; AND
- B) Patient meets at least ONE of the following (i or ii):

- i. Initial therapy. Approve if the patient meets BOTH of the following (a and b):
 - a) Patient has persistent growth failure as defined as BOTH of the following (1 and 2):
 - (1) Patient's baseline height is less than the 5th percentile for age and gender; AND
 - (2) Patient's baseline height velocity is below the 25th percentile over a period of 3 months in infants (≤ 1 year of age) or 6 months in children and adolescents; AND
 - b) Patient has been evaluated by an endocrinologist or a nephrologist; OR
 - ii. Patient is continuing somatropin therapy (i.e., established on somatropin for ≥ 10 months).
Approve if the patient meets BOTH of the following (a and b):
 - a) Patient's height has increased by ≥ 2 cm/year in the most recent year; AND
 - b) Patient's epiphyses are open.
5. **Noonan Syndrome in a Child or Adolescent.** Approve for 1 year if the patient meets BOTH of the following (A and B):
- A) The diagnosis of Noonan syndrome has been confirmed by ONE of the following (i or ii):
 - i. Noonan syndrome has been confirmed with genetic testing; OR
 - ii. If genetic testing does not definitively confirm the diagnosis, the prescriber has made a clinical diagnosis of Noonan syndrome: AND
Note: Clinical diagnosis includes abnormal facial features (high forehead, epicanthic folds, etc.), pulmonary valve stenosis and/or hypertrophic cardiomyopathy, first-degree relative with Noonan syndrome, mild developmental delay.
 - B) Patient meets at least ONE of the following (i or ii):
 - i. Initial therapy. Approve if the patient meets BOTH of the following (a and b):
 - a) Patient's baseline height is less than the 5th percentile using a growth chart for children without Noonan syndrome; AND
 - b) Patient has been evaluated by an endocrinologist; OR
 - ii. Patient is continuing somatropin therapy (i.e., established on somatropin for ≥ 10 months).
Approve if the patient meets BOTH of the following (a and b):
 - a) Patient's height has increased by ≥ 2 cm/year in the most recent year; AND
 - b) Patient's epiphyses are open.
- (3) 6. **Prader-Willi Syndrome.** Approve for 1 year if the patient meets BOTH of the following (A and B):
- A) The diagnosis of Prader-Willi syndrome has been confirmed by genetic testing; AND
 - B) Patient meets at least ONE of the following (i or ii):
 - i. Initial therapy. Approve if the patient (child or adult) has been evaluated by an endocrinologist; OR
 - ii. Patient is continuing somatropin therapy (i.e., established on somatropin for ≥ 10 months).
Approve if the patient meets at least ONE of the following (a or b):
 - a) Child or adolescent. The patient meets BOTH of the following (1 and 2):
 - (1) Patient's height has increased by ≥ 2 cm/year in the most recent year; AND
 - (2) Patient's epiphyses are open; ORNote: When the epiphyses are closed and/or the height velocity is < 2 cm/year, the patient can be reviewed for continuation of therapy as an adult with Prader-Willi syndrome.
 - b) Adult or adolescent whose epiphyses are closed and/or whose height velocity is < 2 cm/year. Patient meets BOTH of the following (1 and 2):
 - (1) This physician must certify that somatropin is not being used for anti-aging therapy or to enhance athletic performance/body building; AND
 - (2) Patient must be evaluated by an endocrinologist or in consultation with an endocrinologist.

7. **Short Stature Homeobox-Containing Gene Deficiency in a Child or Adolescent.** Approve for 1 year if the patient meets BOTH of the following (A and B):
 - A) Patient has short stature homeobox-containing gene deficiency demonstrated by chromosome analysis; AND
 - B) Patient meets at least ONE of the following (i or ii):
 - i. Initial therapy. Approve if the patient meets ALL of the following (a, b, and c):
 - a) Patient's epiphyses are open; AND
 - b) Patient's baseline height is less than the 5th percentile for age and gender; AND
 - c) Patient has been evaluated by an endocrinologist; OR
 - ii. Patient is continuing somatropin therapy (i.e., established on somatropin for ≥ 10 months). Approve if the patient meets BOTH of the following (a and b):
 - a) Patient's height has increased by ≥ 2 cm/year in the most recent year; AND
 - b) Patient's epiphyses are open.

8. **Child Born Small for Gestational Age or with Intrauterine Growth Restriction Including a Child with Silver-Russell Syndrome.** Approve for 1 year if the patient meets BOTH of the following (A and B):
 - A) Patient meets BOTH of the following (i and ii):
 - i. Patient was born small for gestational age, which is defined as birth weight and/or birth length that is > 2 standard deviations (SD) below the mean (< -2 SD) for gestational age and gender; AND
 - ii. Patient did not have sufficient catch-up growth before age 2 to 4 years; AND
 - B) Patient meets at least ONE of the following (i or ii):
 - i. Initial therapy. Approve if the patient meets ALL of the following (a, b, and c):
 - a) Patient is ≥ 2 years of age; AND
 - b) Patient's baseline height is less than the 5th percentile for age and gender; AND
 - c) Patient has been evaluated by an endocrinologist; OR
 - ii. Patient is continuing somatropin therapy (i.e., established on somatropin for ≥ 10 months). Approve if the patient meets at least ONE of the following (a or b):
 - a) Patient is < 12 years of age. Patient's height has increased by ≥ 2 cm/year in the most recent year; OR
 - b) Patient is ≥ 12 years. Patient meets BOTH of the following (1 and 2):
 - (1) Patient's height has increased by ≥ 2 cm/year in the most recent year; AND
 - (2) Patient's epiphyses are open.

9. **Turner Syndrome.** Approve for 1 year if the patient meets BOTH of the following (A and B):
 - A) The diagnosis of Turner's syndrome has been confirmed by karyotype analysis (i.e., chromosome analysis); AND
 - B) Patient meets at least ONE of the following (i or ii):
 - i. Initial therapy. Patient's baseline height is less than the 5th percentile for age and gender; OR
 - ii. Patient is continuing somatropin therapy (i.e., established on somatropin for ≥ 10 months). Approve if the patient meets BOTH of the following (a and b):
 - a) Patient's height has increased by ≥ 2 cm/year in the most recent year; AND
 - b) Patient's epiphyses are open.

- II. Coverage of Genotropin, Humatrope, Norditropin, Nutropin AQ, Omnitrope, Saizen, Zomacton, and Zorbtive (all listed products except Serostim) is recommended in patients who meet the following criteria:

1. Short Bowel Syndrome in an Adult. Approve for 1 month if the patient meets at least ONE of the following (A or B):

A) Initial therapy. Approve if the patient meets ALL of the following (i, ii, and iii):

i. Patient is ≥ 18 years of age; AND

ii. Patient is receiving specialized nutritional support (defined as a high carbohydrate, low-fat diet that is adjusted for individual patient requirements and preferences); AND

iii. Patient is dependent on intravenous parenteral nutrition.

B) Patient is continuing somatropin therapy. Approve if the adult patient responded to somatropin therapy with a decrease in the requirement for specialized nutritional support according to the prescriber.

III. Coverage of Serostim is recommended in those who meet the following criteria:

1. Human Immunodeficiency Virus Infection with Wasting or Cachexia in an Adult. Approve for 6 months if the patient meets ALL of the following (A, B, C, D, E, F, and G):

A) Patient is ≥ 18 years of age; AND

B) Patient meets at least ONE of the following (i, ii, or iii):

i. Documented unintentional weight loss of $\geq 10\%$ from baseline; OR

ii. Patient's weight $< 90\%$ of the lower limit of ideal body weight; OR

iii. Patient's body mass index (BMI) ≤ 20 kg/m²; AND

Note: The following formula can be used to calculate BMI: BMI equals body weight in kg divided by height in meters squared (m²) [i.e., BMI = kg/m²].

C) Patient has wasting or cachexia that is due to malabsorption, poor diet, opportunistic infection, or depression, and other causes have been addressed prior to starting somatropin; AND

D) Patient has been on antiretroviral therapy or highly active antiretroviral treatment for ≥ 30 days prior to beginning Serostim therapy and will continue antiretroviral therapy throughout the course of Serostim treatment; AND

E) Serostim is not being used solely for treatment of alterations in body fat distribution such as increased abdominal girth, lipodystrophy and excess abdominal fat, or buffalo hump; AND

F) Patient meets at least ONE of the following (i or ii):

i. Patient has tried one appetite stimulant or other anabolic agent; OR

Note: Examples of appetite stimulants or other anabolic agents include megestrol acetate, dronabinol, oxandrolone.

ii. Appetite stimulants or other anabolic agents are contraindicated; AND

G) If the patient has previously received treatment with Serostim for this use, patient has been off Serostim therapy for at least 1 month.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Genotropin, Humatrope, Norditropin, Nutropin AQ, Omnitrope, Saizen, Zomacton, Serostim, and Zorbtive is not recommended in the following situations:

Note: For some of the following indications, authorization for coverage is not recommended because the indication is excluded from coverage in a typical pharmacy benefit.

- 1. Acute Critical Illness Due to Complications Following Surgery, Multiple Accidental Trauma, or with Acute Respiratory Failure.**¹⁻⁹ In two placebo-controlled trials in non-growth hormone deficient adults (n = 522) with these conditions, there was a significant increase in mortality (42% vs. 19%) in patients treated with somatropin compared to those on placebo.
- 2. Aging (i.e., Anti-Aging), to Improve Functional Status in an Elderly Patient, and Somatopause.**^{17,18,32,33} Somatropin is not FDA-approved for anti-aging therapy, to improve functional status in elderly patients, or to treat somatopause. Federal law prohibits the distribution or dispensing of somatropin for non-FDA approved uses. There are no long-term studies assessing somatropin efficacy and safety for anti-aging therapy. Short-term therapy with somatropin may improve some measures of body composition, including increased muscle mass, reduced total body fat, improved skin elasticity, and reduced rate of bone demineralization, but somatotropin does not have positive effects on strength, functional capacity, or metabolism. Somatropin is associated with considerable adverse effects in non-growth hormone deficient adults (e.g., carpal tunnel syndrome, soft tissue edema, arthralgias, glucose intolerance, increased serum lipids). Another concern is the possible increased risk of cancer with long-term use of somatropin and the potentiating effects of IGFs on cancer. Somatropin is not indicated for the age-related decrease in growth hormone/IGF-1 status.¹⁶
- 3. Athletic Ability Enhancement.**^{18,34} Somatropin is not FDA-approved for athletic performance enhancement or for body building in nonathletes. Federal law prohibits the distribution or dispensing of somatropin for non-FDA approved uses. Short-term administration of somatropin to increase strength and endurance in athletes is no more effective than training alone and somatropin should not be administered to athletes or other persons for the purpose of enhancing athletic ability or improving personal appearance (i.e., to appear leaner and more muscular). Somatropin has been used in supraphysiologic doses alone or in combination with other performance enhancing drugs (PEDs) in users who are not athletes.³⁴ Use of PEDs has been linked to an increased risk of death and many adverse effects including cardiovascular, psychiatric, metabolic, endocrine, neurologic, infectious, hepatic, renal, and musculoskeletal disorders.
- 4. Central Precocious Puberty.** Children with precocious puberty are often treated with gonadotropin releasing hormone (GnRH) agonists (Lupron® [leuprolide acetate injection]) to suppress pituitary gonadal activity, to slow the advancement of bone age (prevent premature fusion of the epiphyseal growth plates), and to improve adult height. In some patients GnRH agonist therapy may result in marked deceleration of bone growth and may result in adult height that is less than the mid-parental height. Somatropin has been used in girls when growth velocity decreases or if it appears that the targeted adult height will not be attained.³⁵ There are no large well-controlled trials on the efficacy and safety of adding somatropin to GnRH agonist therapy in these children or the effect on final height.^{35,36}
- 5. Chronic Fatigue Syndrome.** There is no evidence of GHD in chronic fatigue syndrome.³⁷
- 6. Congenital Adrenal Hyperplasia (CAH).**^{38,39} The Endocrine Society clinical practice guidelines on CAH due to steroid 21-hydroxylase deficiency recommend against the use of experimental treatment approaches outside of formally approved clinical trials.³⁹ Children with predicted adult height SD $\leq$ -2.25 may be considered for growth-promoting treatments in appropriately controlled trials.

7. **Constitutional Delay of Growth and Puberty.** These children have delayed skeletal maturation and pubertal development. Administering somatropin does not increase adult height (which is usually normal).⁴⁰ Short-term androgen therapy accelerates growth and the rate of pubertal advancement in boys.
8. **Corticosteroid-Induced Short Stature.**¹³ This includes a variety of chronic glucocorticoid-dependent conditions, such as asthma, Crohn's disease,¹³ juvenile rheumatoid arthritis,^{28,41,42} as well as after renal, heart, liver, or bone marrow transplantation.⁴³ Short-term improvement in growth velocity in children with glucocorticoid-induced suppression has been reported with somatropin therapy. Long-term data are not available.¹³ Children being considered for treatment with somatropin should be enrolled in studies that allow careful monitoring and data analysis.
9. **Fibromyalgia.** In one placebo-controlled study, 120 non-GHD adult women with severe fibromyalgia and low levels of IGF-1 were randomized to somatropin 0.006 mg/kg/day for 12 months (dose was adjusted) or placebo for 6 months.⁴⁵ Patients receiving placebo initially were switched to somatropin from Months 6 to 12 (open label). Standard therapy for fibromyalgia was continued. After 6 months, there were no differences between somatropin and placebo in the percentage of patients with fewer than 11 positive tender points, mean number of tender points, intensity of pain in every point evaluated, and other measures. After 12 months of somatropin therapy, 53% of patients had less than 11 positive tender points compared with 33% of patients who received placebo and then somatropin for 6 months ($P < 0.05$). At 18 months follow-up evaluation when somatropin was discontinued, impairment in pain perception worsened in both groups but to a lesser extent in the patients on somatropin for 12 months. Further controlled trials with a longer duration,⁴⁶ with different doses, and using the 2010 American College of Rheumatology criteria for fibromyalgia are needed. Some patients with fibromyalgia may have adult GHD.
10. **Human Immunodeficiency Virus (HIV)-Infected Patient with Alterations in Body Fat Distribution** (e.g., increased abdominal girth, lipodystrophy and excess abdominal fat, buffalo hump).²⁶ Somatropin is not indicated for the treatment of HIV-associated adipose redistribution syndrome (HARS). HARS is a subset of HIV lipodystrophy and is defined as maldistribution of body fat characterized by central fat accumulation (lipohypertrophy) with or without lipoatrophy. In HARS, fat may also accumulate in the upper body subcutaneous area such as the dorsocervical area (buffalo hump). These changes may be associated with metabolic disturbances (insulin resistance, glucose intolerance, dyslipidemia) and belly image distress. Safety and efficacy are not established.
11. **Infertility.**^{47,10} Clinical trials indicate that somatropin is not useful as an adjunct during in vitro fertilization, for induction of ovulation in polycystic ovary syndrome, or for assisted reproductive technology. The authors of a recent meta-analysis concluded there is no evidence of an increased chance of a live birth with use of somatropin.
12. **Obesity.**^{48,49} Somatropin is not indicated for the treatment of obesity. Low growth hormone levels are a consequence of central obesity and not a cause. Obesity is associated with decreased basal and pulsatile release of growth hormone and decreased stimulated growth hormone release. Somatropin therapy does not have significant beneficial effects on obesity in persons without GHD and does not produce significant overall weight loss. Supraphysiologic doses of somatropin have been used to treat obesity. Effects of long-term therapy with somatropin are unknown.
13. **Osteoporosis.**^{50,51} Guidelines for treatment or prevention of osteoporosis do not include recommendations for use of somatropin. In one double-blind trial, 80 postmenopausal women with

osteoporosis (56% of patients [n = 45/80] had a of fractures) were randomized to somatropin 0.33 mg/day or 0.83 mg/day or to placebo for three years.⁵⁰ The double-blind phase was 18 months and patients on somatropin continued drug for another 18 months and patients on placebo stopped at 18 months. Patients were compared with an age-matched random population sample of women (n = 120). All patients received calcium 750 mg, vitamin D 400 units, and hormone replacement therapy. All women were followed for a total of 10 years. Bone mineral density (BMD) increased in the patients receiving somatropin at Years 4 and 5, and after 10 years, BMD decreased to similar levels as before treatment. At 10 years, 28% of women (n = 22/80) had fractures. In the control group, fractures increased from 8% of patients at baseline to 32% of patients after 10 years. At 10 years, 41% of patients (n = 33/80) had stopped hormone replacement therapy; 23% had started bisphosphonates due to fractures, and 3% had received Forteo® (teriparatide injection). Larger studies are needed to determine the effects of somatropin therapy on bone mineral density and fractures in non-growth hormone deficient persons.

14. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Growth Disorders – Increlex Prior Authorization Policy

- Increlex® (mecasermin [rDNA origin] subcutaneous injection – Ipsen)

REVIEW DATE: 12/13/2023

OVERVIEW

Increlex, an insulin-like growth factor (IGF-1), is indicated for the treatment of growth failure in pediatric patients ≥ 2 years of age with the following conditions:¹

- **Primary IGF-1 deficiency**, for patients with severe disease, defined as:
 - Height standard deviation score ≤ -3.0 ; AND
 - Basal IGF-1 standard deviation score ≤ -3.0 ; AND
 - Normal or elevated growth hormone level.
- **Growth hormone gene deletion**, in patients who have developed neutralizing antibodies to growth hormone.

Increlex is given by subcutaneous injection twice daily, shortly before or after a meal or snack. Treatment with Increlex should continue until the epiphyses fuse indicating full growth potential has been achieved.² It is a limitation of use that Increlex is not a substitute to growth hormone for approved growth hormone indications. Increlex is not indicated in secondary forms of IGF-1 deficiency, such as growth hormone deficiency, malnutrition, hypothyroidism, or chronic treatment with pharmacologic doses of anti-inflammatory corticosteroids.¹

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Increlex. Because of the specialized skills required for evaluation and diagnosis of patients treated with Increlex as well as the monitoring required for adverse events and long-term efficacy, initial approval requires Increlex to be prescribed by or in consultation with a physician who specializes in the condition being treated. All approvals are provided for the duration noted below.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Increlex is recommended in those who meet one of the following criteria:

FDA-Approved Indications

34. Insulin-Like Growth Factor-1 (IGF-1) Deficiency – Severe, Primary Disease. Approve for 1 year if the patient meets ONE of the following conditions (A or B):

A) Initial Therapy or Patient Has Been on Increlex < 1 Year. Approve for 1 year if the patient meets ALL of the following (i, ii, iii, iv, v, vi, and vii):

- i. Patient is ≥ 2 years of age; AND
- ii. The epiphyses are open; AND
- iii. Height standard deviation score is ≤ -3.0 at baseline; AND
- iv. Basal IGF-1 standard deviation score is ≤ -3.0 at baseline; AND

12/13/2023

© 2023. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Note: Baseline is prior to initiation of treatment with Increlex. Reference ranges for IGF-1 vary among laboratories and are dependent upon age, gender, and puberty status.

- v. Growth hormone concentration is normal or increased at baseline; AND
 - vi. Patient will not be receiving concurrent treatment with growth hormone; AND
 - vii. The medication is prescribed by or in consultation with a pediatric endocrinologist.
- B) Patient Has Been Receiving Increlex for ≥ 1 Year.** Approve if the patient meets ALL of the following (i, ii, and iii):
- i. Patient's height has increased by ≥ 2 cm/year in the most recent year; AND
 - ii. The epiphyses are open; AND
 - iii. Patient will not be receiving concurrent treatment with growth hormone.

35. Growth Hormone Gene Deletion. Approve for 1 year if the patient meets ONE of the following conditions (A or B):

A) Initial Therapy or Patient Has Been on Increlex < 1 Year. Approve if the patient meets ALL of the following (i, ii, iii, iv, and v):

- i. Patient is ≥ 2 years of age; AND
- ii. The epiphyses are open; AND
- iii. Patient has developed neutralizing antibodies to growth hormone; AND
- iv. Patient will not be receiving concurrent treatment with growth hormone; AND
- v. The medication is prescribed by or in consultation with a pediatric endocrinologist.

B) Patient Has Been Receiving Increlex for ≥ 1 Year. Approve if the patient meets ALL of the following (i, ii, iii, and iv):

- i. Patient's height has increased by ≥ 2 cm/year in the most recent year; AND
- ii. The epiphyses are open; AND
- iii. Patient has developed neutralizing antibodies to growth hormone; AND
- iv. Patient will not be receiving concurrent treatment with growth hormone.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Increlex is not recommended in the following situations:

- 1. Idiopathic Short Stature.** Increlex has not been fully evaluated for this indication. Small studies have suggested some patients may respond to IGF-1 therapy³; however, patients with idiopathic short stature also respond to somatotropin. Somatotropin (monotherapy) is indicated for idiopathic short stature⁴ and there is insufficient evidence to determine the risks and benefits of Increlex for this indication.
- 2. Growth Hormone Deficiency.** Increlex is not a substitute to somatotropin for approved somatotropin uses and is not indicated for use in patients with secondary forms of IGF-1 deficiency, such as growth hormone deficiency.¹
- 3.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Growth Disorders – Ngenla Prior Authorization Policy

- Ngenla® (somatrogen-ghla subcutaneous injection – Pfizer)

REVIEW DATE: 06/12/2024

OVERVIEW

Ngenla, a human growth hormone (hGH) product, is indicated for the treatment of **growth failure due to inadequate secretion of growth hormone (GH)** in pediatric patients ≥ 3 years of age.¹

Disease Overview

Ngenla is a hGH analog, which is made up of the amino acid sequence of hGH with an added three copies of the C-terminal peptide of human chorionic gonadotropin.¹ The addition of the C-terminal peptides leads to a longer half-life. Ngenla binds to the GH receptor, which initiates changes in growth and metabolism. In children with GH deficiency (GHD), somatropin is effective for increasing final adult height.² Somatropin therapy is recommended to normalize adult height and prevent extreme shortness in children and adolescents with GHD. In addition to congenital causes, hypopituitarism may also be caused by radiation therapy; somatropin may be used to improve final height of children who have undergone radiation.^{3,4}

Guidelines

Current guidelines do not specifically address Ngenla. Neither the Pediatric Endocrine Society guidelines for children and adolescents with GHD² (2016) nor the GH Research Society guidelines on children with short stature¹¹ (2019) recommend a specific GH product for GHD. Guidelines recommend the use of GH to normalize adult height and prevent extreme shortness in pediatric patients with GHD.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Ngenla. All reviews will be directed to a clinician (i.e., pharmacist) for verification of criteria. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Ngenla as well as monitoring required for adverse events and long-term efficacy, initial approval requires the patient to be evaluated by a physician who specializes in the condition being treated. hGH is FDA-approved for treatment of a limited number of conditions. The FDA has not approved the use of hGH as therapy for anti-aging, longevity, or cosmetic or performance enhancement. Federal law prohibits the dispensing of hGH for non-approved purposes. A pharmacy's failure to comply with that law could result in significant criminal penalties to the pharmacy and its employees. Accordingly, a pharmacy may decline to dispense prescriptions for hGH when written by a physician or other authorized prescribers who they believe may be involved in or affiliated with the fields of anti-aging, longevity, rejuvenation, cosmetic, performance enhancement, or sports medicine.

Automation: None.

06/12/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Ngenla is recommended in those who meet the following criteria:

FDA-Approved Indication

5. Growth Hormone Deficiency in a Pediatric Patient (≥ 3 years of age to < 18 years of age). Approve for 1 year if the patient meets ONE of the following (A or B):

A) Initial Therapy with any Growth Hormone Agent. Approve if the patient meets ONE of the following (i, ii, iii, iv, or v):

i. Patient meets BOTH of the following (a and b):

a) Patient meets at least ONE of the following [(1) or (2)]:

(1) Patient has had two growth hormone stimulation tests performed with any of the following agents: levodopa, insulin-induced hypoglycemia, arginine, clonidine, or glucagon AND the peak growth hormone response to both tests are < 10 ng/mL; OR

(2) Patient meets BOTH of the following [(a) and (b)]:

(i) Patient has had at least one growth hormone stimulation test performed with any of the following agents: levodopa, insulin-induced hypoglycemia, arginine, clonidine, or glucagon AND the peak growth hormone response to at least one test is < 10 ng/mL; AND

(ii) Patient has at least one risk factor for growth hormone deficiency; AND

Note: Examples of at least one risk factor for growth hormone deficiency includes: the height for age curve has deviated downward across two major height percentiles (e.g., from above the 25th percentile to below the 10th percentile); the child's growth rate is less than the expected normal growth rate based on age and gender; low insulin-like growth factor (IGF)-1 and/or IGFBP-3 levels; the child has a very low peak growth hormone level on provocative testing as defined by the prescribing physician; the child's growth velocity is less than the 10th percentile for age and gender (height velocity percentile is NOT the same as height-for-age percentile); the patient is status post craniopharyngioma resection; the patient has optic nerve hypoplasia; the patient has a growth hormone gene deletion; AND

b) Patient has been evaluated by an endocrinologist.

ii. Patient has undergone brain radiation or tumor resection AND meets BOTH of the following (a and b):

a) Patient meets at least ONE of the following [(1) or (2)]:

(1) Patient meets BOTH of the following [(i) and (ii)]:

(i) Patient has had one growth hormone stimulation test with any of the following agents: levodopa, insulin-induced hypoglycemia, arginine, clonidine, or glucagon; AND

(ii) The peak growth hormone response to at least one test is < 10 ng/mL; OR

(2) Patient has a deficiency in at least one other pituitary hormone (i.e., adrenocorticotrophic hormone, thyroid-stimulating hormone, gonadotropin [luteinizing hormone and/or follicle stimulating hormone deficiency are counted as one deficiency], or prolactin); AND

b) Patient has been evaluated by an endocrinologist.

iii. Patient has congenital hypopituitarism AND meets BOTH of the following (a and b):

a) Patient meets at least ONE of the following [(1), (2), or (3)]:

(1) Patient meets BOTH of the following [(i) and (ii)]:

(i) Patient has had one growth hormone stimulation test with any of the following agents: levodopa, insulin-induced hypoglycemia, arginine, clonidine, or glucagon; AND

- (ii) The peak growth hormone response to at least one test is < 10 ng/mL; OR
 - (2) Patient has a deficiency in at least one other pituitary hormone (i.e., adrenocorticotrophic hormone, thyroid-stimulating hormone, gonadotropin [luteinizing hormone and/or follicle stimulating hormone deficiency are counted as one deficiency], or prolactin); OR
 - (3) Patient has the imaging triad of ectopic posterior pituitary and pituitary hypoplasia with abnormal pituitary stalk; AND
- b) Patient has been evaluated by an endocrinologist.
- iv. Patient has multiple pituitary hormone deficiencies and meets BOTH of the following (a and b):

Note: Growth hormone deficiency may occur in combination with other pituitary hormone deficiencies and is referred to as hypopituitarism, panhypopituitarism, or multiple pituitary hormone deficiency.

 - a) Patient meets at least ONE of the following [(1) or (2)]:
 - (1) Patient has three or more of the following pituitary hormone deficiencies: somatropin (growth hormone), adrenocorticotrophic hormone, thyroid-stimulating hormone, gonadotropin (luteinizing hormone and/or follicle stimulating hormone deficiency are counted as one deficiency), and prolactin; OR
 - (2) Patient meets BOTH of the following [(i) and (ii)]:
 - (i) Patient has had one growth hormone stimulation test with any of the following agents: levodopa, insulin-induced hypoglycemia, arginine, clonidine, or glucagon; AND
 - (ii) The peak growth hormone response to at least one test is < 10 ng/mL; AND
 - b) Patient has been evaluated by an endocrinologist.
- v. Patient has had a hypophysectomy (surgical removal of pituitary gland).
- B) Patient is Currently Receiving Ngenla or is switching to Ngenla from another Growth Hormone Agent (Patient has been established on either therapy for ≥ 10 months). Approve if the patient meets ONE of the following (i or ii):
 - i. Patient is < 12 years of age: Patient's height has increased by ≥ 2 cm/year in the most recent year; OR
 - ii. Patient is ≥ 12 years of age and < 18 years of age: Patient meets BOTH of the following (a and b):
 - a) Patient's height has increased by ≥ 2 cm/year in the most recent year; AND
 - b) Patient's epiphyses are open.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Ngenla is not recommended in the following situations:

- 104. Athletic Ability Enhancement.**⁵ Somatropin and related agents are not FDA-approved for athletic performance enhancement or for body building in non-athletes. Federal law prohibits the distribution or dispensing of somatropin or related agents for non-FDA approved uses.
- 105. Central Precocious Puberty (CPP).** Children with precocious puberty are often treated with gonadotropin releasing hormone (GnRH) agonists (Lupron[®] [leuprolide acetate injection]) to suppress pituitary gonadal activity, to slow the advancement of bone age (prevent premature fusion of the epiphyseal growth plates), and to improve adult height. There are some limited studies which have shown somatropin given in combination with a GnRH analog for patients with CPP and low predicted adult height has been associated with height increases.^{6,7} There are no large well-controlled trials on the efficacy and safety of adding somatropin to GnRH agonist therapy in a patient with CPP.

- 106. Congenital Adrenal Hyperplasia (CAH).**^{8,9} The Endocrine Society clinical practice guidelines on CAH due to steroid 21-hydroxylase deficiency recommend against the use of experimental treatment approaches outside of formally approved clinical trials.⁹ Children with predicted adult height standard deviation ≤ -2.25 may be considered for growth-promoting treatments in appropriately controlled trials.
- 107. Constitutional Delay of Growth and Puberty.** These children have delayed skeletal maturation and pubertal development. Administering somatropin does not increase adult height (which is usually normal).¹⁰ Short-term androgen therapy accelerates growth and the rate of pubertal advancement in boys.
- 108.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Growth Disorders – Skytrofa Prior Authorization Policy

- Skytrofa™ (lonapegsomatropin subcutaneous injection – Ascendis Pharma)

REVIEW DATE: 06/12/2024

OVERVIEW

Skytrofa, a weekly human growth hormone (hGH) product, is indicated for the treatment of pediatric patients ≥ 1 year of age who weigh at least 11.5 kg and have **growth failure due to an inadequate secretion of endogenous growth hormone**.¹

Disease Overview

Lonapegsomatropin is a prodrug of somatropin.¹ In children with GH deficiency (GHD), somatropin is effective for increasing final adult height.² Somatropin therapy is recommended to normalize adult height and avoid extreme shortness in children and adolescents with GHD.² In addition to congenital causes, hypopituitarism may also be caused by radiation therapy; somatropin may be used to improve final height of children who have undergone radiation.^{3,4}

Guidelines

Current guidelines do not specifically address Skytrofa. Neither the Pediatric Endocrine Society guidelines for children and adolescents with GH deficiency² (2016) nor the GH Research Society guidelines on children with short stature¹¹ (2019) recommend a specific GH product for GH deficiency. Guidelines recommend the use of GH to normalize adult height and avoid extreme shortness in pediatric patients with GHD.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Skytrofa. All reviews will be directed to a clinician (i.e., pharmacist) for verification of criteria. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Skytrofa as well as monitoring required for adverse events and long-term efficacy, initial approval requires the patient to be evaluated by a physician who specializes in the condition being treated. hGH is FDA-approved for treatment of a limited number of conditions. The FDA has not approved the use of human growth hormone as therapy for anti-aging, longevity, cosmetic or performance enhancement. Federal law prohibits the dispensing of human growth hormone for non-approved purposes. A pharmacy's failure to comply with that law could result in significant criminal penalties to the pharmacy and its employees. Accordingly, a pharmacy may decline to dispense prescriptions for human growth hormone when written by a physician or other authorized prescribers who they believe may be involved in or affiliated with the fields of anti-aging, longevity, rejuvenation, cosmetic, performance enhancement, or sports medicine.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Skytrofa is recommended in those who meet the following criteria:

FDA-Approved Indication

6. Growth Hormone Deficiency in a Pediatric Patient (≥ 1 year of age to < 18 years of age). Approve for 1 year if the patient meets ONE of the following (A or B):

B) Initial Therapy with any Growth Hormone Agent. Approve if the patient meets ONE of the following (i, ii, iii, iv, or v):

i. Patient meets BOTH of the following (a and b):

a) Patient meets at least ONE of the following [(1) or (2)]:

(1) Patient has had two growth hormone stimulation tests performed with any of the following agents: levodopa, insulin-induced hypoglycemia, arginine, clonidine, or glucagon AND the peak growth hormone response to both tests are < 10 ng/mL; OR

(2) Patient meets BOTH of the following [(a) and (b)]:

(i) Patient has had at least one growth hormone stimulation test performed with any of the following agents: levodopa, insulin-induced hypoglycemia, arginine, clonidine, or glucagon AND the peak growth hormone response to at least one test is < 10 ng/mL; AND

(ii) Patient has at least one risk factor for growth hormone deficiency; AND

Note: Examples of at least one risk factor for growth hormone deficiency includes: the height for age curve has deviated downward across two major height percentiles (e.g., from above the 25th percentile to below the 10th percentile); the child's growth rate is less than the expected normal growth rate based on age and gender; low insulin-like growth factor (IGF)-1 and/or IGFBP-3 levels; the child has a very low peak growth hormone level on provocative testing as defined by the prescribing physician; the child's growth velocity is less than the 10th percentile for age and gender (height velocity percentile is NOT the same as height-for-age percentile); the patient is status post craniopharyngioma resection; the patient has optic nerve hypoplasia; the patient has a growth hormone gene deletion; AND

b) Patient has been evaluated by an endocrinologist.

ii. Patient has undergone brain radiation or tumor resection AND meets BOTH of the following (a and b):

a) Patient meets at least ONE of the following [(1) or (2)]:

(1) Patient meets BOTH of the following [(i) and (ii)]:

(iii) Patient has had one growth hormone stimulation test with any of the following agents: levodopa, insulin-induced hypoglycemia, arginine, clonidine, or glucagon; AND

(iv) The peak growth hormone response to at least one test is < 10 ng/mL; OR

(2) Patient has a deficiency in at least one other pituitary hormone (i.e., adrenocorticotrophic hormone, thyroid-stimulating hormone, gonadotropin [luteinizing hormone and/or follicle stimulating hormone deficiency are counted as one deficiency], or prolactin); AND

b) Patient has been evaluated by an endocrinologist.

iii. Patient has congenital hypopituitarism AND meets BOTH of the following (a and b):

a) Patient meets at least ONE of the following [(1), (2), or (3)]:

(1) Patient meets BOTH of the following [(i) and (ii)]:

(iii) Patient has had one growth hormone stimulation test with any of the following agents: levodopa, insulin-induced hypoglycemia, arginine, clonidine, or glucagon; AND

- (iv) The peak growth hormone response to at least one test is < 10 ng/mL; OR
 - (2) Patient has a deficiency in at least one other pituitary hormone (i.e., adrenocorticotrophic hormone, thyroid-stimulating hormone, gonadotropin [luteinizing hormone and/or follicle stimulating hormone deficiency are counted as one deficiency], or prolactin); OR
 - (3) Patient has the imaging triad of ectopic posterior pituitary and pituitary hypoplasia with abnormal pituitary stalk; AND
- b) Patient has been evaluated by an endocrinologist.
- iv. Patient has multiple pituitary hormone deficiencies and meets BOTH of the following (a and b):

Note: Growth hormone deficiency may occur in combination with other pituitary hormone deficiencies and is referred to as hypopituitarism, panhypopituitarism, or multiple pituitary hormone deficiency.

 - a) Patient meets at least ONE of the following [(1) or (2)]:
 - (1) Patient has three or more of the following pituitary hormone deficiencies: somatropin (growth hormone), adrenocorticotrophic hormone, thyroid-stimulating hormone, gonadotropin (luteinizing hormone and/or follicle stimulating hormone deficiency are counted as one deficiency), and prolactin; OR
 - (2) Patient meets BOTH of the following [(i) and (ii)]:
 - (j) Patient has had one growth hormone stimulation test with any of the following agents: levodopa, insulin-induced hypoglycemia, arginine, clonidine, or glucagon; AND
 - (ii) The peak growth hormone response to at least one test is < 10 ng/mL; AND
 - b) Patient has been evaluated by an endocrinologist.
- v. Patient has had a hypophysectomy (surgical removal of pituitary gland).
- C) Patient is Currently Receiving Skytrofa or is switching to Skytrofa from another Growth Hormone Agent (Patient has been established on either therapy for ≥ 10 months). Approve if the patient meets ONE of the following (i or ii):
 - i. Patient is < 12 years of age: Patient's height has increased by ≥ 2 cm/year in the most recent year; OR
 - ii. Patient is ≥ 12 years of age and < 18 years of age: Patient meets BOTH of the following (a and b):
 - a) Patient's height has increased by ≥ 2 cm/year in the most recent year; AND
 - b) Patient's epiphyses are open.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Skytrofa is not recommended in the following situations:

109. Athletic Ability Enhancement.⁵ Somatropin and related agents are not FDA-approved for athletic performance enhancement or for body building in non-athletes. Federal law prohibits the distribution or dispensing of somatropin or related agents for non-FDA approved uses.

110. Central Precocious Puberty (CPP). Children with precocious puberty are often treated with gonadotropin releasing hormone (GnRH) agonists (Lupron[®] [leuprolide acetate injection]) to suppress pituitary gonadal activity, to slow the advancement of bone age (prevent premature fusion of the epiphyseal growth plates), and to improve adult height. There are some limited studies which have shown somatropin given in combination with a GnRH analog for patients with CPP and low predicted adult height has been associated with height increases.^{6,7} There are no large well-controlled trials on the efficacy and safety of adding somatropin to GnRH agonist therapy in a patient with CPP.

- 111. Congenital Adrenal Hyperplasia (CAH).**^{8,9} The Endocrine Society clinical practice guidelines on CAH due to steroid 21-hydroxylase deficiency recommend against the use of experimental treatment approaches outside of formally approved clinical trials.⁹ Children with predicted adult height standard deviation ≤ -2.25 may be considered for growth-promoting treatments in appropriately controlled trials.
- 112. Constitutional Delay of Growth and Puberty.** These children have delayed skeletal maturation and pubertal development. Administering somatropin does not increase adult height (which is usually normal).¹⁰ Short-term androgen therapy accelerates growth and the rate of pubertal advancement in boys.
- 113.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Growth Disorders – Sogroya Prior Authorization Policy

- Sogroya® (somapacitan-beco subcutaneous injection – Novo Nordisk)

REVIEW DATE: 06/12/2024

OVERVIEW

Sogroya, a long-acting human growth hormone (hGH) analog, is indicated for the treatment of pediatric patients ≥ 2.5 years of age who have growth failure due to inadequate secretion of growth hormone (GH).¹ Sogroya is also indicated for the replacement of endogenous GH in adults with GH deficiency (GHD).

Disease Overview

GHD in Children and Adolescents

Sogroya is a hGH analog.¹ In children with GHD, somatropin is effective for increasing final adult height.² Somatropin therapy is recommended to normalize adult height and avoid extreme shortness in children and adolescents with GHD.² In addition to congenital causes, hypopituitarism may also be caused by radiation therapy; somatropin may be used to improve final height of children who have undergone radiation.^{3,4}

GHD in Adults or Transition Adolescents

Somatropin is indicated for the replacement of endogenous GH in adults with GH, which may present in adults or children as GHD.¹¹ Patients with other anterior pituitary hormone deficiencies are likely to have GHD. In adults, the diagnosis of GHD usually is made in patients with signs and symptoms of hypothalamic-pituitary disease (endocrine, structural, and/or genetic causes); those who have received cranial irradiation or tumor treatment; or those with traumatic brain injury or subarachnoid hemorrhage.^{11,12} Onset may be in adulthood or childhood. In childhood, the goal of somatropin therapy is primarily for statural growth. When final adult height is attained, somatropin therapy is no longer required for statural growth. Transition is used to describe the period in adolescence after growth is completed and the need for continued replacement into adulthood is assessed. Confirmatory GH stimulation testing may not be required in patients, such as those with congenital/genetic GHD or multiple pituitary hormone deficiencies. When persistent GHD is documented after completion of adult height, somatropin therapy should be continued to attain full skeletal and muscle maturation during the transition period from childhood to adulthood.¹¹ In adults with GHD, somatropin replacement therapy improves abnormalities in substrate metabolism, body composition, and physical and psychosocial function.^{11,12} GH is not approved by the FDA for the treatment of other conditions in adults who may have a low GH response to GH provocative testing (such as obesity, aging, or depression) or to improve athletic performance.^{3,5}

Guidelines

Current guidelines do not specifically address Sogroya. Neither the Pediatric Endocrine Society guidelines for children and adolescents with GH deficiency² (2016) nor the GH Research Society guidelines on children with short stature¹⁵ (2019) recommend a specific GH product for GHD. Both publications note that newer long-acting GH preparations may reduce the frequency of injections. The American Association of Clinical Endocrinologists and the American College of Endocrinology guidelines for management of GHD in adults and patients transitioning from pediatric to adult care¹⁶ (2019) also do not prefer one GH agent over another. These guidelines state that when the clinician is suspicious of adult GHD, establishing a diagnosis is essential before replacement with GH. Adult GHD is associated with numerous adverse metabolic abnormalities (abdominal obesity, reduced lean body mass, increased peripheral insulin

06/12/2024

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

resistance, impaired cardiac performance) which may contribute to increased cardiovascular morbidity and mortality.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Sogroya. All reviews will be directed to a clinician (i.e., pharmacist) for verification of criteria. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Sogroya as well as monitoring required for adverse events and long-term efficacy, initial approval requires the patient to be evaluated by a physician who specializes in the condition being treated. Human growth hormone is FDA-approved for treatment of a limited number of conditions. The FDA has not approved the use of human growth hormone as therapy for anti-aging, longevity, cosmetic or performance enhancement. Federal law prohibits the dispensing of human growth hormone for non-approved purposes. A pharmacy's failure to comply with that law could result in significant criminal penalties to the pharmacy and its employees. Accordingly, a pharmacy may decline to dispense prescriptions for human growth hormone when written by a physician or other authorized prescribers who they believe may be involved in or affiliated with the fields of anti-aging, longevity, rejuvenation, cosmetic, performance enhancement, or sports medicine.

Documentation: Documentation is required for use of Sogroya as noted in the criteria as **[documentation required]**. Documentation may include, but is not limited to, chart notes, prescription claims records, prescription receipts, and/or other information. For patient cases in which documentation is required, if this documentation has been previously received upon a prior coverage review, the documentation requirement is considered to be met.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Sogroya is recommended in those who meet the following criteria:

FDA-Approved Indication

7. **Growth Hormone Deficiency in a Child or Adolescent (≥ 2.5 years of age).** Approve for 1 year if the patient meets ONE the following (A or B):
 - C) **Initial Therapy with any Growth Hormone Agent.** Approve if the patient meets ONE of the following (i, ii, iii, iv, or v):
 - i. Patient meets BOTH of the following (a and b):
 - a) Patient meets ONE of the following [(1) or (2)]:
 - (1) Patient has had two growth hormone stimulation tests performed with any of the following agents: levodopa, insulin-induced hypoglycemia, arginine, clonidine, or glucagon AND the peak growth hormone response to both tests are < 10 ng/mL; OR
 - (2) Patient meets BOTH of the following criteria [(a) and (b)]:
 - (v) Patient has had at least one growth hormone stimulation test performed with any of the following agents: levodopa, insulin-induced hypoglycemia, arginine, clonidine, or glucagon AND the peak growth hormone response to at least one test is < 10 ng/mL; AND
 - (vi) Patient has at least one risk factor for growth hormone deficiency; AND
 - Note:** Examples of at least one risk factor for growth hormone deficiency includes: the height for age curve has deviated downward across two major height

percentiles (e.g., from above the 25th percentile to below the 10th percentile); the child's growth rate is less than the expected normal growth rate based on age and gender; low insulin-like growth factor (IGF)-1 and/or IGFBP-3 levels; the child has a very low peak growth hormone level on provocative testing as defined by the prescribing physician; the child's growth velocity is less than the 10th percentile for age and gender (height velocity percentile is NOT the same as height-for-age percentile); the patient is status post craniopharyngioma resection; the patient has optic nerve hypoplasia; the patient has a growth hormone gene deletion; AND

- b)** Patient has been evaluated by an endocrinologist.
- ii.** Patient has undergone brain radiation or tumor resection AND meets BOTH of the following (a and b):
 - a)** Patient meets at least ONE of the following [(1) or (2)]:
 - (1)** Patient meets BOTH of the following [(i) and (ii)]:
 - (i)** Patient has had at least one growth hormone stimulation test performed with any of the following agents: levodopa, insulin-induced hypoglycemia, arginine, clonidine, or glucagon; AND
 - (ii)** The peak growth hormone response to at least one test is < 10 ng/mL; OR
 - (2)** Patient has a deficiency in at least one other pituitary hormone (i.e., adrenocorticotrophic hormone, thyroid-stimulating hormone, gonadotropin [luteinizing hormone and/or follicle stimulating hormone deficiency are counted as one deficiency], or prolactin); AND
 - b)** Patient has been evaluated by an endocrinologist.
- iii.** Patient has congenital hypopituitarism AND meets BOTH of the following (a and b):
 - a)** Patient meets at least ONE of the following [(1), (2), or (3)]:
 - (1)** Patient meets BOTH of the following [(i) and (ii)]:
 - (i)** Patient has had at least one growth hormone stimulation test performed with any of the following agents: levodopa, insulin-induced hypoglycemia, arginine, clonidine, or glucagon; AND
 - (ii)** The peak growth hormone response to at least one test is < 10 ng/mL; OR
 - (2)** Patient has a deficiency in at least one other pituitary hormone (i.e., adrenocorticotrophic hormone, thyroid-stimulating hormone, gonadotropin [luteinizing hormone and/or follicle stimulating hormone deficiency are counted as one deficiency], or prolactin); OR
 - (3)** Patient has the imaging triad of ectopic posterior pituitary and pituitary hypoplasia with abnormal pituitary stalk; AND
 - b)** Patient has been evaluated by an endocrinologist.
- iv.** Patient has multiple pituitary hormone deficiencies and meets BOTH of the following (a and b):

Note: Growth hormone deficiency may occur in combination with other pituitary hormone deficiencies and is referred to as hypopituitarism, panhypopituitarism, or multiple pituitary hormone deficiency.

 - a)** Patient meets at least ONE of the following [(1) or (2)]:
 - (1)** Patient has three or more of the following pituitary hormone deficiencies: somatotropin (growth hormone), adrenocorticotrophic hormone, thyroid-stimulating hormone, gonadotropin (luteinizing hormone and/or follicle stimulating hormone deficiency are counted as one deficiency), and prolactin; OR
 - (2)** Patient meets BOTH of the following [(i) and (ii)]:
 - (i)** Patient had one growth hormone stimulation test with any of the following agents: levodopa, insulin-induced hypoglycemia, arginine, clonidine, or glucagon; AND
 - (ii)** The peak growth hormone response to at least one test is < 10 ng/mL; AND

- b) Patient has been evaluated by an endocrinologist.
 - v. Patient has had a hypophysectomy (surgical removal of pituitary gland).
- B) Patient is Currently Receiving Sogroya or is switching to Sogroya from another Growth Hormone Agent (Patient has been established on either therapy for ≥ 10 months). Approve if the patient meets ONE of the following (i, ii, or iii):
 - i. Patient is < 12 years of age: Patient's height has increased by ≥ 2 cm/year in the most recent year; OR
 - ii. Patient is ≥ 12 years of age and < 18 years of age: Patient meets BOTH of the following (a and b):
 - a) Patient's height has increased by ≥ 2 cm/year in the most recent year; AND
 - b) Patient's epiphyses are open; OR
 - iii. Patient is ≥ 18 years of age. Patient meets ALL of the following (a, b, and c):
 - a) Patient's height has increased by ≥ 2 cm/year in the most recent year; AND
 - b) Patient's epiphyses are open; AND
 - c) Mid-parental height has not been attained.
Note: Mid-parental height is the father's height plus the mother's height divided by 2, plus 2.5 inches if male or minus 2.5 inches if female.
Note: Adolescents and young adults with childhood onset growth hormone deficiency who have completed linear growth may continue receiving Sogroya therapy as a transition adolescent or as an adult. See criteria for Growth Hormone Deficiency in an adult or transition adolescent.

2. **Growth Hormone Deficiency in an Adult or Transition Adolescent.** Approve for 1 year if the patient meets ALL of the following (A, B, C, and D):
 - A) The endocrinologist must certify that growth hormone therapy is not being prescribed for anti-aging therapy or to enhance athletic ability or for body building; AND
 - B) Patient must have a diagnosis of growth hormone deficiency that is ONE of the following (i or ii):
[documentation required for all elements]
 - iii. Childhood onset; OR
 - iv. Adult onset that results from one of the following: growth hormone deficiency alone or multiple hormone deficiencies (hypopituitarism) resulting from pituitary disease, hypothalamic disease, pituitary surgery, cranial radiation therapy, tumor treatment, traumatic brain injury, or subarachnoid hemorrhage; AND
 - C) Patient meets at least ONE of the following (i, ii, or iii):
 - iv. Patient (adult or transition adolescent) has known perinatal insults OR congenital or genetic defects; **[documentation required]** OR
 - v. Patient meets ALL of the following (a, b, and c):
 - d) Patient (adult onset or transition adolescent) has three or more of the following pituitary hormone deficiencies: Adrenocorticotrophic hormone, thyroid-stimulation hormone, gonadotropin deficiency (luteinizing hormone and/or follicle stimulating hormone deficiency are counted as one deficiency), and prolactin **[documentation required]**; AND
 - e) The age and gender adjusted serum insulin-like growth factor-1 is below the lower limit of the normal reference range for the reporting laboratory **[documentation required]**; AND
 - f) Other causes of low serum insulin-like growth factor-1 have been excluded (e.g., malnutrition, prolonged fasting, poorly controlled diabetes mellitus, hypothyroidism, hepatic insufficiency, oral estrogen therapy); OR
 - vi. Patient meets at least ONE of the following (a or b):
 - a) Adult. Patient has had a negative response to at least ONE of the following standard growth hormone stimulation tests (1, 2, 3, 4, 5, or 6) **[documentation required for all elements]**:

Note: If the patient has had a previous trial of an arginine test with a peak response of ≤ 0.4 mcg/L, this would meet the criteria for a negative response to a growth hormone stimulation test.

- (1) Insulin tolerance test (obtaining at least 3 growth hormone levels in at least a 60 minute timeframe [not including a level at timeframe zero], with adequate hypoglycemia being achieved) with peak response ≤ 5.0 mcg/L; OR
- (2) Glucagon stimulation test (obtaining at least 3 growth hormone levels in at least 180 minute timeframe [not including a level at timeframe zero]) with peak response ≤ 3.0 mcg/L AND the patient's body mass index (BMI) is < 25 kg/m²; OR
- (3) Glucagon stimulation test (obtaining at least 3 growth hormone levels in at least 180 minute timeframe [not including a level at timeframe zero]) with a peak response ≤ 3.0 mcg/L AND the patient's BMI is ≥ 25 kg/m² and ≤ 30 kg/m² with, according to the prescriber, a high pretest probability of growth hormone deficiency; OR
- (4) Glucagon stimulation test (obtaining at least 3 growth hormone levels in at least 180 minute timeframe [not including a level at timeframe zero]) with a peak response ≤ 1.0 mcg/L AND the patient's BMI is ≥ 25 kg/m² and ≤ 30 kg/m² with, according to the prescriber, a low pretest probability of growth hormone deficiency; OR
- (5) Glucagon stimulation test (obtaining at least 3 growth hormone levels in at least 180 minute timeframe [not including a level at timeframe zero]) with peak response ≤ 1.0 mcg/L AND the patient's BMI is > 30 kg/m²; OR
- (6) Macrilen (macimorelin oral solution) test (obtaining at least 4 growth hormone levels in at least a 90 minute timeframe [not including a level at timeframe zero]) with peak responses < 2.8 ng/mL (2.8 mcg/L) AND the patient's BMI is ≤ 40 kg/m².

Note: The following formula can be used to calculate BMI: BMI equals body weight in kg divided by height meters squared (m²) [i.e., BMI = kg/m²]; OR

- b) Transition adolescent. Patient meets BOTH of the following (1 and 2): **[documentation required for all elements]**:

Note: The transition period is the time from late puberty to establishment of adult muscle and bone composition, and encompasses attainment of adult height.

Note: If the patient has had a trial of a Macrilen test with a peak response of < 2.8 ng/mL (mcg/L), this would meet the criteria for a negative response to a growth hormone stimulation test.

- (3) Patient has been off growth hormone therapy for at least 1 month before retesting with a growth hormone stimulation test; AND
- (4) Patient meets at least ONE of the following responses to growth hormone stimulation testing (i, ii, iii, iv, v or vi):
 - (vii) Insulin tolerance test (obtaining at least 3 growth hormone levels in at least a 60 minute timeframe [not including a level at timeframe zero], with adequate hypoglycemia being achieved) with peak response ≤ 5.0 mcg/L; OR
 - (viii) Glucagon stimulation test (obtaining at least 3 growth hormone levels in at least 180 minute timeframe [not including a level at timeframe zero]) with peak response ≤ 3.0 mcg/L AND the patient's body mass index (BMI) is < 25 kg/m²; OR
 - (ix) Glucagon stimulation test (obtaining at least 3 growth hormone levels in at least 180 minute timeframe [not including a level at timeframe zero]) with a peak response of ≤ 3.0 mcg/L AND the patient's BMI is ≥ 25 kg/m² and ≤ 30 kg/m² with, according to the prescriber, a high pretest probability of growth hormone deficiency; OR
 - (x) Glucagon stimulation test (obtaining at least 3 growth hormone levels in at least 180 minute timeframe [not including a level at timeframe zero]) with a peak

response ≤ 1.0 mcg/L AND the patient's BMI is ≥ 25 kg/m² and ≤ 30 kg/m² with, according to the prescriber, a low pretest probability of growth hormone deficiency; OR

(xi) Glucagon stimulation test (obtaining at least 3 growth hormone levels in at least 180 minute timeframe [not including a level at timeframe zero]) with peak response ≤ 1.0 mcg/L AND the patient's BMI is > 30 kg/m²; OR

(xii) If both the insulin tolerance test AND glucagon stimulation test are contraindicated, the arginine test can be used (obtaining at least 3 growth hormone levels in at least 120 minute timeframe [not including a level at timeframe zero]) with a peak response ≤ 0.4 mcg/L; AND

D) Patient has been evaluated by an endocrinologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Sogroya is not recommended in the following situations:

Note: For some of the following indications, authorization for coverage is not recommended because this indication is excluded from coverage in a typical pharmacy benefit.

- 1. Acute Critical Illness Due to Complications Following Surgery, Multiple Accidental Trauma, or with Acute Respiratory Failure.**¹ Sogroya is contraindicated in acute critical illness after open-heart surgery, abdominal surgery, multiple accidental trauma, or those with acute respiratory failure because of the risk of increased mortality.
- 2. Aging (i.e., Anti-Aging), to Improve Functional Status in an Elderly Patient, and Somatopause.**^{13,14,17,18} Somatropin is not FDA-approved for anti-aging therapy, to improve functional status in elderly patients, or to treat somatopause. Federal law prohibits the distribution or dispensing of somatropin for non-FDA approved uses. There are no long-term studies assessing somatropin efficacy and safety for anti-aging therapy. Short-term therapy with somatropin may improve some measures of body composition, including increased muscle mass, reduced total body fat, improved skin elasticity, and reduced rate of bone demineralization, but somatotropin does not have positive effects on strength, functional capacity, or metabolism. Somatropin is associated with considerable adverse effects in non-growth hormone deficient adults (e.g., carpal tunnel syndrome, soft tissue edema, arthralgias, glucose intolerance, increased serum lipids). Another concern is the possible increased risk of cancer with long-term use of somatropin and the potentiating effects of insulin growth factor (IGFs) on cancer. Somatropin is not indicated for the age-related decrease in growth hormone/IGF-1 status.¹²
- 3. Athletic Ability Enhancement.**⁵ Somatropin is not FDA-approved for athletic performance enhancement or for body building in nonathletes. Federal law prohibits the distribution or dispensing of somatropin for non-FDA approved uses. Short-term administration of somatropin to increase strength and endurance in athletes is no more effective than training alone and somatropin should not be administered to athletes or other persons for the purpose of enhancing athletic ability or improving personal appearance (i.e., to appear leaner and more muscular). Somatropin has been used in supraphysiologic doses alone or in combination with other performance enhancing drugs (PEDs) in users who are not athletes.³⁴ Use of PEDs has been linked to an increased risk of death and many adverse effects including cardiovascular, psychiatric, metabolic, endocrine, neurologic, infectious, hepatic, renal, and musculoskeletal disorders.
- 4. Central Precocious Puberty (CPP).** Children with precocious puberty are often treated with gonadotropin releasing hormone (GnRH) agonists (Lupron® [leuprolide acetate injection]) to suppress pituitary gonadal activity, to slow the advancement of bone age (prevent premature fusion of the

epiphyseal growth plates), and to improve adult height. There are some limited studies which have shown somatropin given in combination with a GnRH analog for patients with CPP and low predicted adult height has been associated with height increases.^{6,7} There are no large well-controlled trials on the efficacy and safety of adding somatropin to GnRH agonist therapy in a patient with CPP.

5. **Chronic Fatigue Syndrome.** There is no evidence of GHD in chronic fatigue syndrome.¹⁹
6. **Congenital Adrenal Hyperplasia (CAH).**^{8,9} The Endocrine Society clinical practice guidelines on CAH due to steroid 21-hydroxylase deficiency recommend against the use of experimental treatment approaches outside of formally approved clinical trials.⁹ Children with predicted adult height standard deviation ≤ -2.25 may be considered for growth-promoting treatments in appropriately controlled trials.
7. **Constitutional Delay of Growth and Puberty.** These children have delayed skeletal maturation and pubertal development. Administering somatropin does not increase adult height (which is usually normal).¹⁰ Short-term androgen therapy accelerates growth and the rate of pubertal advancement in boys.
8. **Fibromyalgia.** In one placebo-controlled study, 120 non-GHD adult women with severe fibromyalgia and low levels of IGF-1 were randomized to somatropin 0.006 mg/kg/day for 12 months (dose was adjusted) or placebo for 6 months.²⁰ Patients receiving placebo initially were switched to somatropin from Months 6 to 12 (open label). Standard therapy for fibromyalgia was continued. After 6 months, there were no differences between somatropin and placebo in the percentage of patients with fewer than 11 positive tender points, mean number of tender points, intensity of pain in every point evaluated, and other measures. After 12 months of somatropin therapy, 53% of patients had less than 11 positive tender points compared with 33% of patients who received placebo and then somatropin for 6 months ($P < 0.05$). At 18 months follow-up evaluation when somatropin was discontinued, impairment in pain perception worsened in both groups but to a lesser extent in the patients on somatropin for 12 months. Further controlled trials are needed with a longer duration,²¹ with different doses, and using the 2010 American College of Rheumatology criteria for fibromyalgia. Some patients with fibromyalgia may have adult GHD.
9. **Infertility.**^{22,23} Clinical trials indicate that somatropin is not useful as an adjunct during *in vitro* fertilization, for induction of ovulation in polycystic ovary syndrome, or for assisted reproductive technology. The authors of a recent meta-analysis concluded there is no evidence of an increased chance of a live birth with use of somatropin.
10. **Obesity.**^{24,25} Somatropin is not indicated for the treatment of obesity. Low growth hormone levels are a consequence of central obesity and not a cause. Obesity is associated with decreased basal and pulsatile release of growth hormone and decreased stimulated growth hormone release. Somatropin therapy does not have significant beneficial effects on obesity in persons without GHD and does not produce significant overall weight loss. Supraphysiologic doses of somatropin have been used to treat obesity. Effects of long-term therapy with somatropin are unknown.
11. **Osteoporosis.**^{13,14} Guidelines for treatment or prevention of osteoporosis do not include recommendations for use of somatropin. In one double-blind trial, 80 postmenopausal women with osteoporosis (56% of patients [$n = 45/80$] had a of fractures) were randomized to somatropin 0.33 mg/day or 0.83 mg/day or to placebo for 3 years.¹³ The double-blind phase was 18 months and patients on somatropin continued drug for another 18 months and patients on placebo stopped at 18 months. Patients were compared with an age-matched random population sample of women ($n = 120$). All patients received calcium 750 mg, vitamin D 400 units, and hormone replacement therapy. All women

were followed for 10 years total. Bone mineral density increased in the patients receiving somatropin at Years 4 and 5, and after 10 years, had decreased to similar levels as before treatment. At 10 years, 28% of women (n = 22/80) had fractures. In the control group, fractures increased from 8% of patients at baseline to 32% of patients after 10 years. At 10 years, 41% of patients (n = 33/80) had stopped hormone replacement therapy; 23% had started bisphosphonates due to fractures, and 3% had received Forteo® (teriparatide injection). Larger studies are needed to determine the effects of somatropin therapy on bone mineral density and fractures in non-growth hormone deficient persons.

12. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Growth Disorders – Voxzogo Prior Authorization Policy

- Voxzogo™ (vosoritide subcutaneous injection – BioMarin)

REVIEW DATE: 11/20/2024

OVERVIEW

Voxzogo, a C type natriuretic peptide (CNP) analog, is indicated **to increase linear growth in pediatric patients with achondroplasia** with open epiphyses.¹

Disease Overview

Achondroplasia is the most common form of disproportionate short stature in humans.² It is a primary skeletal dysplasia caused by a mutation in the fibroblast growth factor receptor 3 (FGFR3) gene; this mutation leads to impaired endochondral ossification. Achondroplasia occurs in approximately 1 in 20,000 to 30,000 live births.³ It occurs as a result of a spontaneous mutation in 80% of patients (i.e., both parents are of normal height).⁴ In the remaining 20% of patients, the mutation is inherited from a parent. Achondroplasia is characterized by short stature, long-bone shortening in the proximal upper and lower extremities, and macrocephaly. The diagnosis can be confirmed by molecular testing.⁵ In the pivotal trial for Voxzogo, achondroplasia was confirmed by genetic testing in all patients.² Additionally, exclusion criteria included evidence of decreased growth velocity (< 1.5 cm/year) or of growth plate closure through bilateral lower extremity X-rays.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Voxzogo. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Voxzogo as well as the monitoring required for adverse events and long-term efficacy, approval requires Voxzogo to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Voxzogo is recommended in those who meet the following criteria:

FDA-Approved Indication

8. **Achondroplasia.** Approve for 1 year if the patient meets ONE of the following (A or B):
- A) Initial Therapy or Patient Has Been on Voxzogo for < 1 Year. Approve if the patient meets ALL of the following (i, ii, iii, iv, v, and vi):
- i. Patient is < 18 years of age; AND
 - ii. The diagnosis of achondroplasia has been confirmed by genetic testing with an identifiable mutation in the fibroblast growth factor receptor type 3 (FGFR3) gene; AND
 - iii. Patient's epiphyses are open; AND
 - iv. Patient will not have limb-lengthening surgery during treatment with Voxzogo; AND

11/20/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- v. The prescriber has confirmed the patient is able to drink approximately 240 to 300 mL of fluid in the hour prior to Voxzogo administration; AND
 - vi. The medication is prescribed by or in consultation with a pediatric endocrinologist.
- B) Patient Has Been Receiving Voxzogo for ≥ 1 Year.** Approve if the patient meets ALL of the following (i, ii, iii, iv, v, vi, and vii):
- i. Patient is < 18 years of age; AND
 - ii. The diagnosis of achondroplasia has been confirmed by genetic testing with an identifiable mutation in the fibroblast growth factor receptor type 3 (FGFR3) gene; AND
 - iii. Patient's epiphyses are open; AND
 - iv. Patient will not have limb-lengthening surgery during treatment with Voxzogo; AND
 - v. The prescriber has confirmed the patient is able to drink approximately 240 to 300 mL of fluid in the hour prior to Voxzogo administration; AND
 - vi. The medication is prescribed by or in consultation with a pediatric endocrinologist; AND
 - vii. Patient's most recent annualized growth velocity continues to be above their baseline annualized growth velocity value (i.e., before the patient started on Voxzogo).

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Voxzogo is not recommended in the following situations:

- 114. Hypochondroplasia, Thanatophoric Dysplasia, or other Short Stature Conditions other than Achondroplasia (e.g., Trisomy 21, Pseudoachondroplasia).** Voxzogo is only indicated for patients with achondroplasia.¹ There is a small published Phase 2 trial showing some efficacy for children with hypochondroplasia.¹¹ There is no evidence Voxzogo is effective for other short stature conditions.
- 115. Concurrent Treatment with Growth Hormone (e.g., somatropin), Long-Acting Growth Hormone (e.g., Ngenla[®] [somatrogen-ghla], Skytrofa[®] [lonapegsomatropin], Sogroya[®] [somapacitan-becol]), or Insulin-like Growth Factor- 1 (IGF-1) [i.e., Increlex[®] {mecasermin}] Agents.** Growth hormone agents and Increlex are NOT indicated to increase growth in patients with achondroplasia.⁶⁻¹⁰ Additionally, there are no available studies demonstrating the safety or efficacy of concurrent use with Voxzogo.
- 116.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hemangeol Prior Authorization with Step Therapy Policy

- Hemangeol® (propranolol hydrochloride oral solution [4.28 mg/mL] – Pierre Fabre)

REVIEW DATE: 11/13/2024

OVERVIEW

Hemangeol, a beta-adrenergic blocker, is indicated for the treatment of proliferating infantile hemangioma requiring systemic therapy.¹ Initiate treatment at ages 5 weeks to 5 months.

Disease Overview

Infantile hemangiomas are common pediatric vascular tumors;^{2,3} they may occur in up to 5% of infants.⁴ The pathogenesis is not clearly known but may be due to the proliferation of endothelial cells present in the chorionic villi of the placenta.³ Onset may occur as early as a few weeks after birth. The most significant growth occurs between 1 month to 3 months of age.⁴ Although hemangiomas may occur anywhere on the body, most occur on the head and neck. Some are small and resolve on their own without treatment.²⁻⁴ Others, due to their size the location, are disfiguring (e.g., those present in the facial region), cause functional impairment (e.g., periorbital infantile hemangiomas), or lead to permanent skin changes (scarring).²⁻⁴ Early active interventions should be sought for infantile hemangiomas that are problematic (ideally by before 5 weeks of age).³

Guidelines

The American Academy of Pediatrics published clinical practice guidelines for the management of infantile hemangiomas in 2019.⁴ Regarding pharmacological therapy, oral propranolol is the treatment of choice for problematic infantile hemangiomas that require systemic treatment. Oral prednisolone or prednisone may be used for infantile hemangiomas if there are contraindications or if patients have experienced an inadequate response to propranolol. Intralesional injection of triamcinolone and/or betamethasone may be used to treat focal, bulky infantile hemangiomas during proliferation or in selected critical anatomic locations (e.g., the lip). Topical timolol may be utilized to treat some thin and/or superficial infantile hemangiomas. Surgery and/or laser treatment may be used for selected patients. Early intervention (ideally by 1 month of age) is recommended for infants who may have problematic infantile hemangiomas. It is notable that infantile hemangiomas have a maximum growth potential between 1 and 3 months of age; the majority of growth is complete by 5 months of age. However, deeper infantile hemangiomas may have a slightly later onset and more prolonged duration of growth. By 5 to 12 months of age, most infantile hemangiomas have stopped growing and are beginning to involute. Changes in color of the infantile hemangiomas may change from red to milky-white or gray. Lesions gradually flatten and shrink. In general, infantile hemangioma involution is complete by 4 years of age in 90% of patients. Extended therapy may need to account for the remainder of the infantile hemangiomas.

Safety

Hemangeol is contraindicated in the following conditions; premature infants with corrected age < 5 weeks; infants weighing less than 2 kg; asthma or of bronchospasm; heart rate < 80 beats per minute, greater than first degree heart block, or decompensated heart failure; blood pressure < 50/30 mmHg; and pheochromocytoma.

POLICY STATEMENT

11/13/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Prior Authorization is recommended for prescription benefit coverage of Hemangeol. There is also a Step Therapy component which applies only to a patient ≥ 6 months of age. When Step Therapy applies, a trial of generic propranolol is required prior to Hemangeol.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Hemangeol recommended in those who meet the following criteria:

FDA-Approved Indication

- 9. Infantile Hemangioma, Proliferating.** Approve for 1 year if the patient meets BOTH of the following (A and B):
- A)** Patient is less than 6 years of age; AND
 - B)** If the patient is greater than or equal to 6 months of age, patient has tried generic propranolol.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Hemangeol is not recommended in the following situations:

- 117.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hematology – Adzynma Prior Authorization Policy

- Adzynma™ (ADAMTS13 recombinant-krhn intravenous infusion – Takeda)

REVIEW DATE: 12/04/2024

OVERVIEW

Adzynma, a human recombinant “A disintegrin and metalloproteinase with thrombospondin motifs 13” (ADAMTS13) product, is indicated for prophylactic or on demand enzyme replacement therapy for the management of congenital thrombotic thrombocytopenia purpura in adult and pediatric patients.¹

Disease Overview

Congenital thrombotic thrombocytopenic purpura is a very rare, inherited blood clotting disorder (prevalence of ≥ 0.5 cases per million population).²⁻⁴ It is due to a mutation in the ADAMTS13 gene that makes a key enzyme, also named ADAMTS13, that regulates blood clotting. The condition results from severe hereditary deficiency ($< 10\%$ of normal activity) of ADAMTS13. The deficiency in this enzyme causes blood clots to form in the small blood vessels throughout the body. Symptoms typically start in infancy or early childhood, but in some cases may develop in adulthood and can initially manifest during pregnancy. Patients with congenital thrombotic thrombocytopenic purpura may experience severe bleeding episodes, strokes, and damage to vital organs. The condition can be fatal if not managed. Treatment for congenital thrombotic thrombocytopenic purpura currently involves prophylactic plasma-based therapy to reduce the risk of clotting/bleeding by replenishing the absent/low ADAMTS13 enzyme; on-demand therapy can also be given.

Guidelines

Adzynma has not been specifically addressed in guidelines post FDA-approval.⁵ The International Society on Thrombosis and Haemostasis (ISTH) has guidelines for the treatment of thrombotic thrombocytopenic purpura (2020). For patients with congenital thrombotic thrombocytopenic purpura who are in remission, the panel suggests either plasma infusion or a watch and wait strategy. For patients with congenital thrombotic thrombocytopenic purpura who are pregnant, the panel recommends prophylactic treatment over no prophylactic treatment. In this clinical scenario, plasma infusion is recommended over Factor VIII products.

The British Society of Haematology published guidelines for the diagnosis and management of thrombotic thrombocytopenic purpura and thrombotic microangiopathies.⁶ The diagnosis of congenital thrombotic thrombocytopenic purpura is defined by ADAMTS13 activity < 10 IU/dL, no anti-ADAMTS13 antibodies, and confirmation of homozygous or compound heterozygous variants in the ADAMTS13 gene. For an acute episode, solvent detergent plasma infusion is recommended. ADAMTS13 prophylaxis should be considered for all patients with an individualized approach to dose and frequency according to symptoms, whether overt or non-overt. For pregnant women with congenital thrombotic thrombocytopenic purpura, regular solvent/detergent fresh frozen plasma replacement therapy should be given prophylactically to prevent clinical relapse.

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Adzynma. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Adzynma as well as the monitoring required for adverse events and long-term efficacy, approval requires Adzynma to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Documentation: Documentation is required for use of Adzynma as noted in the criteria as **[documentation required]**. Documentation may include but is not limited to chart notes, laboratory data, genetic test results, and/or other information.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Adzynma is recommended in those who meet the following criteria:

FDA-Approved Indication

10. Congenital Thrombotic Thrombocytopenic Purpura. Approve for 1 year if the patient meets ALL the following (A, B, C, and D):

A) At baseline (prior to therapy) ADAMTS13 activity is < 10% (< 10 IU/dL) **[documentation required]**; AND

Note: Baseline refers to before any treatment was received, such as Adzynma or plasma-based therapies.

B) Patient does not have anti-ADAMTS13 autoantibodies as determined by a diagnostic test **[documentation required]**; AND

C) Patient has a pathogenic variant or a mutation in the ADAMTS13 gene **[documentation required]**; AND

Note: Pathogenic variants or gene mutations are usually homozygous or compound heterozygous.

D) Medication is prescribed by or in consultation with a hematologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Adzynma is not recommended in the following situations:

118. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hematology – Aphexda Prior Authorization Policy

- Aphexda™ (motixafortide subcutaneous injection – BioLineRx)

REVIEW DATE: 10/02/2024

OVERVIEW

Aphexda, a hematopoietic stem cell mobilizer, is indicated in combination with filgrastim (granulocyte colony stimulating factor) to **mobilize hematopoietic stem cells to the peripheral blood for collection and subsequent autologous transplantation in patients with multiple myeloma.**¹

Disease Overview

Multiple myeloma is a cancer formed by malignant plasma cells found in the bone marrow.^{2,3} In 2023, it is estimated that there will be approximately 35,730 new cases of multiple myeloma and 12,590 deaths due to the disease. There are many therapies available for multiple myeloma. Autologous stem cell transplantation (ASCT) has a vital role in the treatment of multiple myeloma. The outcomes of ASCT relies on the collection of sufficient hematopoietic stem and progenitor cells, usually from peripheral blood.

Guidelines

Aphexda is addressed in the National Comprehensive Cancer Network guidelines for Hematopoietic Cell Transplantation (version 2.2024 – August 30, 2024).⁴ Aphexda is listed as an alternative in combination with G-CSF to mobilize hematopoietic stem cells for autologous donors (category 2A) in patients with multiple myeloma; the regimen is more specific for filgrastim.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Aphexda. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Aphexda as well as the monitoring required for adverse events and long-term efficacy, approval requires Aphexda to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Aphexda is recommended in those who meet the following criteria:

FDA-Approved Indication

- 11. Multiple Myeloma.** Approve for 1 month if the patient meets ALL of the following (A, B, C, and D):
- A) Patient is ≥ 18 years of age; AND
 - B) The agent is utilized for mobilization of hematopoietic stem cells for subsequent autologous transplantation; AND
 - C) Use is in combination with filgrastim; AND

10/02/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Note: Examples of filgrastim products include Granix (tbo-filgrastim subcutaneous injection) and Neupogen (filgrastim subcutaneous injection and intravenous infusion), as well as related biosimilars.

D) Medication is prescribed by a hematologist and/or a stem cell transplant specialist physician.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Aphexda is not recommended in the following situations:

- 119. Leukemia.** Aphexda may cause mobilization of leukemia cells and subsequent contamination of the apheresis product.¹ Aphexda is not intended for hematopoietic stem cell mobilization and harvest in patients with leukemia.
- 120.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hematology – Cablivi Prior Authorization Policy

- Cablivi® (caplacizumab-yhdp intravenous infusion and subcutaneous injection – Genzyme/Sanofi)

REVIEW DATE: 02/21/2024

Overview

Cablivi, a von Willebrand factor (vWF)-directed antibody fragment, is indicated for the treatment of **acquired thrombotic thrombocytopenic purpura (aTTP)** in adults, in combination with plasma exchange and immunosuppressive therapy.¹

Disease Overview

Thrombotic thrombocytopenic purpura (TTP) is a rare but potentially fatal blood disorder.²⁻⁴ TTP may be caused by an inherited severe deficiency of plasma ADAMTS13 (A Disintegrin And Metalloproteinase with ThromboSpondin-1 motif, member 13) activity resulting from mutations; this is referred to as hereditary or congenital TTP. More commonly, TTP is acquired and due to autoantibodies that inhibit plasma ADAMTS13 activity, referred to as immune-mediated (or acquired) TTP (iTTP). Reduced ADAMTS13 activity leads to accumulation of ultra-large vWF multimers in the blood, which bind to platelets and lead to excessive platelet clumping in the microvasculature, resulting in multi-organ failure and death.²⁻⁵ Cablivi is a nanobody that targets the ultra-large vWF and inhibits the interaction between vWF and platelets, thereby preventing vWF platelet adhesion and consumption.^{1,5,6}

Dosing Information

Two doses of Cablivi are given on the first day of plasma exchange, followed by one dose of Cablivi per day during plasma exchange; treatment is continued for 30 days after the last plasma exchange session.¹ If, after the initial treatment course, there are signs of persistent underlying disease such as suppressed ADAMTS13 levels, Cablivi therapy may be extended for a maximum of 28 days. Cablivi should be discontinued if the patient experiences more than two recurrences of aTTP while on Cablivi.

Guidelines/Recommendations

The standard of care for treatment of aTTP is plasma exchange and glucocorticoids.⁷ Plasma exchange removes the ultra-large vWF and autoantibodies and replenishes ADAMTS13, and immunosuppressants inhibit autoantibody formation. Rituximab can also be added to the aTTP treatment regimen. Rituximab has been shown to reduce the incidence of aTTP relapse by diminishing the production of anti-ADAMTS13 antibodies and restoring ADAMTS13 activity.²

The International Society on Thrombosis and Haemostasis (ISTH) formed a multidisciplinary panel including hematologists and pathologists with clinical expertise in the diagnosis and management of TTP, clinicians from other relevant disciplines, and patient representatives to issue recommendations about treatment of TTP (2020).⁸ For patients with aTTP or iTTP experiencing an acute event (first event or relapse), the panel suggests using Cablivi over not using Cablivi. The panel stressed that Cablivi should only be given under the guidance of an experienced clinician, ideally a TTP expert (e.g., a hematologist or pathologist specialized in transfusion medicine with previous experience in treating the disease).

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Cablivi. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Cablivi as well as the monitoring required for adverse events and efficacy, approval requires Cablivi to be prescribed by or in consultation with a physician who specializes in the condition being treated. Note that one course of treatment consists of Cablivi to be administered in conjunction with plasma exchange and Cablivi to be administered for up to 60 days (one dose per day) following the last plasma exchange session.

Automation: None.

Recommended Authorization Criteria

Coverage of Cablivi is recommended in those who meet the following criteria:

FDA-Approved Indication

18. Acquired Thrombotic Thrombocytopenic Purpura. Approve for one course of treatment (up to 60 days following the last plasma exchange session) if the patient meets the following (A, B, C, D, and E):

K) Patient is ≥ 18 years of age; AND

L) Cablivi was initiated in the inpatient setting, in combination with plasma exchange therapy; AND

M) Patient is currently receiving at least one immunosuppressive therapy; AND

Note: Examples include systemic corticosteroids, rituximab (or a rituximab product), cyclosporine, cyclophosphamide, mycophenolate mofetil, hydroxychloroquine, bortezomib.

N) If the patient has previously received Cablivi, he/she has not had more than two recurrences of acquired thrombotic thrombocytopenic purpura while on Cablivi; AND

O) The medication is prescribed by or in consultation with a hematologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Cablivi is not recommended in the following situations:

26. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hematology – Ceprotin Prior Authorization Policy

- Ceprotin® (protein C concentrate [human] intravenous infusion – Takeda)

REVIEW DATE: 12/04/2024

OVERVIEW

Ceprotin is indicated for **severe congenital protein C deficiency** for the prevention and treatment of venous thrombosis and purpura fulminans in neonates, pediatric and adult patients.¹

Disease Overview

Severe congenital protein C deficiency is an autosomal recessive disorder associated with biallelic loss-of-function variants in the protein C (*PROC*) gene which result in a deficiency of protein C, a natural anticoagulant.^{2,4} The predicted incidence is 1 per 4 million births.² The prevalence is likely lower due to early fetal death or undiagnosed neonatal deaths. The condition typically presents with purpura fulminans and disseminated intravascular coagulation within 72 hours of birth, but may occur in later infancy. Many infants experience retinal and cerebral vessel thrombosis. The normal adult range for plasma protein C levels is 0.65 to 1.35 IU/mL. In severe congenital protein deficiency, protein C levels by definition are < 0.01 IU/mL and are often undetectable. In some cases, biallelic *PROC* variants results in moderate reduction of protein C levels (0.01 to 0.2 IU/mL) and may present in infancy with purpura fulminans or in adolescence or adults with recurrent various thromboembolic disease. Diagnosis is based on characteristic symptoms and detailed family history, in addition to measurement of protein C activity or antigen levels.³ It is critical to exclude any acquired reason for protein C deficiency, which is more common than congenital protein C deficiency.^{2,3} Potential causes of acquired deficiency include vitamin K antagonists (e.g., warfarin), vitamin K deficiency, chronic liver disease, severe infection, or disseminated intravascular coagulopathy.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Ceprotin. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Ceprotin as well as the monitoring required for adverse events and long-term efficacy, approval requires Ceprotin to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Ceprotin is recommended in those who meet the following criteria:

FDA-Approved Indication

43. Protein C Deficiency, Severe. Approve for 1 year if the patient meets ALL of the following (A, B, C, and D)

- i. The diagnosis of protein C deficiency is confirmed by at least ONE of the following (i, ii, or iii):

12/04/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- a) Plasma protein C activity below the lower limit of normal based on the age-specific reference range for the reporting laboratory; OR
- b) Plasma protein C antigen below the lower limit of normal based on the age-specific reference range for the reporting laboratory; OR
- c) Genetic testing demonstrating biallelic pathogenic variants in the *PROC* gene; AND

ii. Acquired causes of protein C deficiency have been excluded; AND

Note: Examples of acquired causes of protein C deficiency include recent use of vitamin K antagonists (e.g., warfarin) within 30 days, vitamin K deficiency, chronic liver disease, recent thrombosis, recent surgery, or disseminated intravascular coagulation.

iii. According to the prescriber, patient has a current or prior of symptoms associated with severe protein C deficiency (e.g., purpura fulminans, thromboembolism); AND

iv. Ceprotin is being prescribed by or in consultation with a hematologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Ceprotin is not recommended in the following situations:

121. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hematology – Coagadex Prior Authorization Policy

- Coagadex® (coagulation Factor X [human] intravenous infusion – BPL)

REVIEW DATE: 12/04/2024

OVERVIEW

Coagadex, a plasma-derived coagulation Factor X product, is indicated in hereditary Factor X deficiency for use in adults and children for:¹

- **On-demand treatment and control** of bleeding episodes.
- **Perioperative management** of bleeding in patients with mild and moderate hereditary Factor X deficiency.
- **Routine prophylaxis** to reduce the frequency of bleeding episodes.

Disease Overview

Factor X deficiency, a rare autosomal recessive inherited bleeding disorder, affects approximately 1 in 500,000 to 1,000,000 patients worldwide.²⁻⁷ The Factor X protein has a key role to assist in activating the enzymes that are key in clot formation. In this condition, blood does not clot properly. Patients experience easy bruising, nose or mouth bleeds, and bleeding after trauma or surgery. Among patients with severe Factor X deficiency, umbilical cord bleeding can be one of the first signs; however, bleeding may present at any time. Serious bleeds include spontaneous head bleeds, spinal cord bleeds, and gastrointestinal bleeds. Women who have the condition may experience heavy menstrual bleeding or have menorrhagia. During pregnancy, women may miscarry during the first trimester or have other complications during labor and delivery. However, Factor X deficiency has an equal prevalence in men and women. It is recommended to maintain trough levels of around 20% to 30%. Other treatments include fresh frozen plasma, prothrombin complex concentrates, and Coagadex.

Guidelines

The National Bleeding Disorders Foundation Medical and Scientific Advisory Council has guidelines for the treatment of hemophilia and other bleeding disorders (revised October 2024).⁸ Coagadex is recommended in patients who have Factor X deficiency.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Coagadex. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Coagadex as well as the monitoring required for adverse events and long-term efficacy, approval requires Coagadex to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Coagadex is recommended in those who meet the following criteria:

12/04/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

FDA-Approved Indication

- 12. Hereditary Factor X Deficiency.** Approve for 1 year if the agent is prescribed by or in consultation with a hematologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Coagadex is not recommended in the following situations:

- 122.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hematology – Corifact Prior Authorization Policy

- Corifact® (Factor XIII Concentrate [human] intravenous infusion – CSL Behring)

REVIEW DATE: 12/04/2024

OVERVIEW

Corifact, a Factor XIII concentrate, is indicated in congenital Factor XIII deficiency in adult and pediatric patients for:¹

- **Peri-operative management** of surgical bleeding.
- **Routine prophylactic** treatment.

Disease Overview

Congenital Factor XIII deficiency is caused by defects in both Factor XIII_A and Factor XIII_B genes.^{2,3} However, most cases are due to genetic alterations on the Factor XIII_A gene. The estimated prevalence of Factor XIII_A deficiency is one case in 2 million patients. Clinical symptoms include delayed wound healing, bleeding of soft and subcutaneous tissue, recurrent spontaneous miscarriage, and central nervous system (CNS) bleeding, which may be life-threatening. If patients have severe Factor XIII deficiency, early manifestations include bleeding from the umbilical cord or CNS. Prospective data showed that a level of 30% Factor XIII clotting activity is an adequate therapeutic target for most patients. Treatment of Factor XIII deficiency involves use of fresh frozen plasma, cryoprecipitate, Corifact, or Tretten® (coagulation Factor XIII_A-Subunit [recombinant] intravenous infusion).

Guidelines

The National Bleeding Disorders Foundation Medical and Scientific Advisory Council has guidelines for the treatment of hemophilia and other bleeding disorders (revised October 2024).⁴ Corifact is recommended in patients who have Factor XIII deficiency.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Corifact. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Corifact as well as the monitoring required for adverse events and long-term efficacy, approval requires Corifact to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Corifact is recommended in those who meet the following criteria:

12/04/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

FDA-Approved Indication

- 13. Congenital Factor XIII Deficiency.** Approve for 1 year if the agent is prescribed by or in consultation with a hematologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Corifact is not recommended in the following situations:

- 123.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hematology – Enjaymo Prior Authorization Policy

- Enjaymo® (sutimlimab-jome intravenous infusion – Bioverativ/Sanofi)

REVIEW DATE: 01/03/2024

OVERVIEW

Enjaymo, a classical complement inhibitor, is indicated for the treatment of hemolysis in **cold agglutinin disease** in adults.¹

Disease Overview

Cold agglutinin disease is a rare autoimmune hemolytic anemia.²⁻⁴ Primary cold agglutinin disease is a B-cell lymphoproliferative disorder in which autoantibodies are produced against erythrocyte surface antigens. Primary cold agglutinin disease is distinct from secondary disease, termed cold agglutinin syndrome, which can occur with underlying conditions such as malignancy, infection, and autoimmune diseases.^{2,3} Diagnosis of cold agglutinin disease is defined by chronic hemolysis, a cold agglutinin titer ≥ 64 at 4°C, and typical findings on direct antibody test (DAT), which include strong positivity for complement protein C3d and negativity (or only weak positivity) for immunoglobulin G.²⁻⁴ Secondary causes of cold agglutinin syndrome should be excluded. Importantly, patients without chronic hemolysis or circulatory symptoms do not have cold agglutinin disease, even in the presence of positive DAT.² Symptoms include cold-induced circulatory symptoms, which can range from slight acrocyanosis to severe Raynaud phenomena. Anemia is generally considered mild to moderate with a median hemoglobin (Hb) of 8.9 g/dL; however, the lower tertile Hb was 8.0 g/dL and ranged to as low as 4.5 g/dL.^{2,4}

Clinical Efficacy

In the pivotal CARDINAL trial (published) [n = 24], patients were required to have a confirmed diagnosis of cold agglutinin disease based on chronic hemolysis, typical DAT findings, and a recent blood transfusion within the prior 6 months.^{1,5-7} Patients were also required to have a baseline hemoglobin level < 10 g/dL and total bilirubin above normal. Approximately two-thirds of patients had failed other therapies (e.g., rituximab). The Phase III CADENZA trial (published) [n = 42] also required chronic hemolysis, as well as the DAT and cold agglutinin titer findings described above; however, recent history of blood transfusion was not required.^{1,8}

Guidelines

An international consensus guideline for autoimmune hemolytic anemias was published in 2020.⁹ The guideline was published prior to the approval of Enjaymo and no formal recommendation is made regarding its place in therapy, although positive Phase I data are acknowledged. It is noted that clinical and histological assessment, as well as radiologic examinations as needed, are necessary to rule out cold agglutinin syndrome secondary to malignant disease. Treatment of cold agglutinin syndrome involves supportive care and management of the underlying disease. For treatment of cold agglutinin disease, asymptomatic patients should be managed with watchful waiting. For symptomatic patients (i.e., those with anemia, transfusion, or circulatory symptoms), rituximab is the best-documented first-line treatment and may be given alone or in combination with bendamustine. For second-line treatment, the combination of rituximab plus bendamustine is recommended (if not given in the first-line setting). Alternatively, rituximab monotherapy may be repeated for patients who previously responded for at least 1 year. Rituximab plus fludarabine is an option for fit, elderly patients. There are no evidence-based therapies for the third-line setting.

01/03/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Enjaymo. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Enjaymo as well as the monitoring required for adverse events and long-term efficacy, approval requires Enjaymo to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Enjaymo is recommended in those who meet the following criteria:

FDA-Approved Indication

14. Cold Agglutinin Disease. Approve for 1 year if the patient meets the following (A, B, C, D, E, F, G, and H):

- A) Patient is ≥ 18 years of age; AND
- B) Patient weighs ≥ 39 kg; AND
- C) Patient has a of at least one sign or symptom associated with cold agglutinin disease; AND
Note: Examples include symptomatic anemia (e.g., anemia associated with fatigue, weakness, shortness of breath, heart palpitations, lightheadedness, chest pain), acrocyanosis, Raynaud's syndrome, hemoglobinuria, disabling circulatory symptoms, or a major adverse vascular event (e.g., thrombosis).
- D) According to the prescriber, the patient has evidence of chronic hemolysis; AND
- E) Patient meets the following diagnostic criteria (i and ii):
 - i. Direct antibody test strongly positive for C3d and negative or only weakly positive for immunoglobulin G; AND
 - ii. Cold agglutinin antibody titer ≥ 64 at 4°C (approximately 40°F); AND
- F) At baseline (prior to the initiation of Enjaymo), patient meets both of the following (i and ii):
 - i. Hemoglobin ≤ 10 g/dL; AND
 - ii. Total bilirubin above the upper limit of normal, based on the reference range for the reporting laboratory; AND
- G) According to the prescriber, secondary causes of cold agglutinin syndrome have been excluded; AND
Note: Examples of secondary causes of cold agglutinin syndrome include infection, rheumatologic diseases, and active hematologic malignancies.
- H) Enjaymo is prescribed by or in consultation with a hematologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Enjaymo is not recommended in the following situations:

124. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

- POLICY:** Hematology – Fibrinogen Products Prior Authorization Policy
- Fibryga® (fibrinogen [human] intravenous injection – Octapharma)
 - RiaSTAP® (fibrinogen concentrate [human] intravenous injection – CSL Behring)

REVIEW DATE: 08/21/2024

OVERVIEW

Fibryga and RiaSTAP, human fibrinogen concentrates, are indicated for treatment of acute bleeding episodes in patients with **congenital fibrinogen deficiency**, including afibrinogenemia and hypofibrinogenemia.^{1,2} Fibryga is also FDA-approved for fibrinogen supplementation in bleeding patients with **acquired fibrinogen deficiency**.² Both the Fibryga and RiaSTAP prescribing information note that these agents are not indicated for dysfibrinogenemia.

Disease Overview

Congenital deficiencies in fibrinogen (also known as Factor I) can be quantitative or qualitative.³⁻⁵ Quantitative disorders include afibrinogenemia (absence of circulating fibrinogen) and hypofibrinogenemia (low levels of circulating fibrinogen). By contrast, dysfibrinogenemia is a qualitative deficiency in which fibrinogen levels are adequate, but function is impaired. In all cases, clinical presentation is variable; however, bleeding and thromboembolism are possible.^{6,7} Treatment of fibrinogen deficiency is generally on-demand for acute bleeding episodes, although effective prophylaxis has been used in high-risk patients (e.g., secondary prevention after cerebral hemorrhage, primary prevention during pregnancy to prevent miscarriage).

Guidelines

Guidelines are available from the British Committee for Standards in Haematology (2014); the guideline was written prior to approval of Fibryga.⁸ Fibrinogen concentrate (e.g., RiaSTAP) may be required to treat or prevent bleeding. Cryoprecipitate is noted to be similarly effective to fibrinogen concentrate but may be associated with transfusion reactions or volume overload.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of fibrinogen products (Fibryga, RiaSTAP). All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with fibrinogen products as well as the monitoring required for adverse events and long-term efficacy, approval requires these agents to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

- I. Coverage of Fibryga and RiaSTAP is recommended in those who meet the following criteria:

08/21/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

FDA-Approved Indication

15. Congenital Fibrinogen Deficiency (Factor I Deficiency), Including Afibrinogenemia and Hypofibrinogenemia. Approve for 1 year if the medication is prescribed by or in consultation with a hematologist.

II. Coverage of Fibryga is recommended in those who meet the following criteria:

1. Acquired Fibrinogen Deficiency. Approve for 1 year if the medication is prescribed by or in consultation with a hematologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Fibryga and RiaSTAP is not recommended in the following situations:

125. Concomitant Use of Fibryga and RiaSTAP. There are no data to support concomitant use of these products.

126. Dysfibrinogenemia. In dysfibrinogenemia, patients have adequate levels of fibrinogen but dysfunctional clotting.^{3,4} Fibryga and RiaSTAP are not indicated in dysfibrinogenemia.^{1,2}

127. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hematology – Gene Therapy – Casgevy Prior Authorization Policy

- Casgevy™ (exagamglogene autotemcel intravenous infusion – Vertex/CRISPR Therapeutics)

REVIEW DATE: 01/31/2024; selected revision 03/20/2024, 09/25/2024

OVERVIEW

Casgevy, an autologous hematopoietic stem cell-based gene therapy, is indicated for the following uses:¹

- **Sickle cell disease** in patients ≥ 12 years of age with recurrent vaso-occlusive crises (VOCs).
- **Transfusion-dependent beta-thalassemia** (TDT) in patients ≥ 12 years of age.

Casgevy is given one-time (per lifetime) as a single dose, which contains a minimum of 3×10^6 cluster of differentiation 34+ (CD34+) cells/kg of body weight. Casgevy is given as an intravenous (IV) infusion. The manufacturing time (which includes quality control) for Casgevy can take up to 6 months. However, the entire process can take 8 months or longer as patients need to undergo mobilization and apheresis procedures and myeloablative conditioning prior to Casgevy infusion.

Casgevy is prepared from the patient's own hematopoietic stem cells, which are obtained via apheresis procedure(s).^{1,2} The CD34+ cells collected from the patient are modified *ex-vivo* by highly specific clustered, regularly interspaced, short palindromic repeats (CRISPR) and CRISPR-associated protein 9 nucleases (CRISPR/Cas9)-mediated gene editing. CRISPR/Cas9 specifically edits the B-cell lymphoma/leukemia 11A (BCL11A) gene. After Casgevy infusion, the edited CD34+ cells engraft in the bone marrow and differentiate to erythroid lineage cells with reduced BCL11A expression. Downregulation of BCL11A expression in the erythroid progenitors of the bone marrow results in reduced BCL11A protein levels, which leads to an increase in γ -globin expression and increased fetal hemoglobin (HbF) production. In patients with TDT, γ -globin production improves the α -globin to non α -globin imbalance, thereby reducing ineffective erythropoiesis and hemolysis and increasing total hemoglobin (Hb) levels, which eliminates the dependence on regular red blood cell (RBC) transfusions. In patients with sickle cell disease, increased HbF levels ($\geq 20\%$) are protective against disease complications, including preventing VOCs.²

Disease Overview

Sickle Cell Disease

Sickle cell disease is a group of inherited RBC disorders characterized by the presence of a mutated Hb subunit beta gene.³⁻⁵ Healthy RBCs are round and contain Hb. In contrast, in a patient with sickle cell disease, RBCs are sickle-shaped and die early, resulting in a constant shortage of RBCs. Furthermore, the sickle-shaped RBCs aggregate in the bloodstream, causing vaso-occlusion, which deprive downstream tissues of nutrients and oxygen, resulting in tissue ischemia, organ damage, and hemolysis (which leads to anemia). In the US, approximately 100,000 persons have the condition and it is estimated 20,000 patients have severe sickle cell disease.^{2,3}

Patients with severe sickle cell disease have one of the following genotypes: β^S/β^S , β^S/β^0 , β^S/β^+ .²⁻⁵ These patients have recurrent VOCs/vaso-occlusive events, while receiving appropriate supportive care (e.g., pain management, hydroxyurea). Management of sickle cell disease focuses on preventing and treating pain episodes and other complications; symptomatic treatment includes use of analgesics, fluids (hydration), oxygen supplementation, and blood transfusion. Allogeneic hematopoietic stem cell transplantation

(HSCT), a potentially curative therapy, requires a stem cell donor, typically a human leukocyte antigen (HLA)-matched donor; less than 20% of patients with sickle cell disease have a suitable donor.² Pharmacologic treatments for sickle cell disease include Adakveo® (crizanlizumab-tmca IV infusion), Endari® (L-glutamine oral powder), hydroxyurea, and Oxbryta® (voxelotor tablets and tablets for oral suspension).⁶⁻¹⁰

Transfusion-Dependent Beta-Thalassemia

The condition of beta-thalassemia is a group of recessively inherited blood disorders caused by beta-globin gene mutations that either reflect a reduced (β^+) or relative lack (β^0) of production of functional beta-globin.¹¹ The attenuated or lack of Hb results in chronic anemia of varying degrees of severity and insufficient delivery of oxygen to the body. Those with severe anemia may require lifelong RBC transfusions and regular iron chelation to prevent iron overload. The extremely low Hb levels can lead to many types of symptoms and health-related issues (e.g., dizziness, weakness, fatigue, increased cardiac effort, tachycardia, poor growth) or ineffective erythropoiesis (e.g., bone changes, massive splenomegaly). An estimated 3,000 persons in the US have beta-thalassemia and slightly less than one-half of the patients are dependent on RBC transfusions.

Clinical Efficacy

Sickle Cell Disease

Casgevy is being evaluated in an ongoing, single-dose, multicenter study involving adolescents and adults with sickle cell disease.^{1,2} Eligible patients underwent mobilization and apheresis procedures to collect CD34+ stem cells for Casgevy manufacturing, followed by myeloablative conditioning with busulfan and infusion of Casgevy. All of the enrolled patients had one of the following genotypes: β^S/β^S , β^S/β^0 , or β^S/β^+ . In addition, all patients had severe sickle cell disease, as defined by the occurrence of at least two of the following VOC events per year during the 2-year period before screening, while receiving appropriate supportive care: acute pain that required a visit to a medical facility and administration of pain medications (opioids or IV nonsteroidal anti-inflammatory drugs) or RBC transfusions; acute chest syndrome; priapism lasting more than 2 hours and requiring a visit to a medical facility; or splenic sequestration. Key exclusion criteria were patients with the following: clinically significant and active bacterial, viral, fungal, or parasitic infection; advanced liver disease; history or presence of Moyamoya disease; and prior or current malignancy or myeloproliferative disorder or significant immunodeficiency disorder. The primary efficacy set (PES) [n = 31] was composed of patients who received Casgevy infusion and were followed for at least 16 months after infusion.¹ At the interim analysis (June 2023 cut-off date), the median age of patients in the PES was 21 years; 23% of patients were adolescents (≥ 12 and < 18 years of age). At baseline, the annualized (median) rate of severe VOCs during the previous 2 years was 3.5 and the annualized (median) rate of hospitalizations due to severe VOCs during the previous 2 years was 2.0. All patients received plerixafor for mobilization and busulfan for myeloablative conditioning. Casgevy was administered as an IV infusion. The primary efficacy endpoint was the proportion of patients who did not experience a severe VOC for at least 12 consecutive months within the first 24 months after Casgevy infusion (VF12 responders) and the key secondary endpoint was the proportion of patients who did not require hospitalization due to severe VOCs for at least 12 consecutive months within the first 24 months after Casgevy infusion (HF12 responders). Evaluation of both endpoints began 60 days after the last RBC transfusion for post-transplant support or sickle cell disease support. The VF12 response rate was 93.5% (n = 29/31) and all 30 patients evaluable for HF12 response achieved this endpoint.

Transfusion-Dependent Beta-Thalassemia

Casgevy is being studied in an ongoing, open-label, multicenter, single-arm study involving adolescents and adults with TDT.¹ Eligible patients underwent mobilization and apheresis procedures to collect CD34+ stem cells for Casgevy manufacturing, followed by myeloablative conditioning and Casgevy infusion. Patients were followed for 24 months after Casgevy infusion. All of the enrolled patients had a history of requiring transfusions of 100 mL/kg/year or more of packed RBCs in the 2 years prior to enrollment or requiring at least 10 units/year of packed RBCs in the 2 years prior to enrollment. In addition, patients had one of the following genotypes for beta-thalassemia: β^0/β^0 -like (including β^0/β^+ [IVS-I-110] and β^+ [IVS-I-110]/ β^+ [IVS-I-110]) and non- β^0/β^0 -like. The PES [n = 35] was composed of patients who received Casgevy infusion and had adequate follow-up for evaluation of the primary efficacy endpoint. At the interim analysis (conducted based on January 2023 data cut-off), the median age of the patients was 20 years; 31.4% of the patients were adolescents (≥ 12 and < 18 years of age). At baseline, the annualized (median) RBC transfusion volume was 205 mL/kg and the annualized (median) number of RBC transfusion episodes was 17. All of the patients received a granulocyte-colony stimulating factor (G-CSF) and plerixafor to mobilize stem cells for apheresis and busulfan for myeloablative conditioning. Casgevy (median dose of 7.5×10^6 cells/kg) was administered as an IV infusion. At the interim analysis, the median (minimum, maximum) duration of follow-up was 23.8 (16.1, 48.1) months after Casgevy infusion. The primary efficacy endpoint was the proportion of patients achieving transfusion independence for at least 12 consecutive months (TI12), which was defined as maintaining weighted average Hb ≥ 9 g/dL without RBC transfusions for at least 12 consecutive months, within the first 24 months after Casgevy infusion. Evaluation of this endpoint started 60 days after the last RBC transfusion for post-transplant support or TDT disease management. In total, 32 of 35 patients achieved TI12; the responder rate was 91.4% (98.3% one-sided confidence interval [CI]: 75.7%, 100%). All of the patients who achieved TI12 remained transfusion-independent, with a median duration of 20.8 months and normal mean weighted average total Hb levels of 13.1 g/dL. The median time to last RBC transfusion for patients who achieved TI12 was 30 days after Casgevy infusion. The three patients who did not achieve TI12 had reductions in annualized RBC transfusion volume requirements of 79.8%, 83.9%, and 97.9%, respectively, compared to baseline requirements. In addition, the three patients had reductions in annualized transfusion frequency of 78.6%, 67.4%, and 94.6%, respectively, compared to baseline requirements.

Guidelines

Sickle Cell Disease

Sickle cell disease guidelines have not incorporated gene therapies following their FDA approval. The American Society of Hematology (ASH) released evidence-based recommendations for stem cell transplantation for patients with sickle cell disease in 2021.¹² ASH notes that it is unclear how gene therapies will affect sickle cell disease outcomes, including organ complications and if broader access to curative therapy will alter the trajectory of sickle cell disease outcomes. ASH notes that while success rates after allogeneic HSCT are increasing, survival rates in patients receiving disease-modifying medications (e.g., hydroxyurea, L-glutamine, Adakveo, Oxbryta) and supportive care are also improving. More than 90% of patients who have undergone HSCT (predominantly using HLA-identical family donors) have been cured of sickle cell disease, as reported in short-term follow-up. Allogeneic HSCT is an established therapeutic option for patients with sickle cell disease with a clinical indication and an HLA-identical family donor. However, for the majority of patients, there are no suitable donors.

Transfusion-Dependent Beta-Thalassemia

Guidelines have not addressed Casgevy. In 2021, the Thalassaemia International Federation published guidelines for the management of TDT.¹³

- **Chelation therapy** was cited as an effective treatment modality in improving survival, decreasing the risk of heart failure, and decreasing morbidities from transfusion-induced iron overload. The

optimal chelation regimen should be individualized and will vary among patients and their clinical status.

- **Allogeneic hematopoietic stem cell transplant (HSCT)** should be offered to patients with beta-thalassemia at an early age, before complications due to iron overload have developed if an HLA-identical sibling is available. In some clinical circumstances, a matched unrelated donor can be adequate.
- **Reblozyl®** (luspatercept-aamt subcutaneous injection), an erythroid maturation agent, can be considered for patients ≥ 18 years of age who require regular RBC transfusions.
- **Zynteglo™** (betibeglogene autotemcel intravenous infusion), when available, may be an option for selected patients. Examples include young patients (12 to 17 years of age) with a β^+ genotype who do not have an HLA-compatible sibling donor. Also, Zynteglo can be considered in patients 17 to 55 years of age with a β^+ genotype who do not have severe comorbidities and are at risk or ineligible to undergo allogeneic HSCT but can otherwise undergo an autologous gene therapy procedure with an acceptable risk.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Casgevy. Approval is recommended for those who meet the Criteria for the listed indications.

Because of the specialized skills required for evaluation and diagnosis of patients treated with Casgevy as well as the specialized training required for administration of Casgevy, approval requires Casgevy to be prescribed by a physician who specializes in the condition being treated. All approvals are provided for one-time (per lifetime) as a single dose. The approval duration is 1 year to allow for an adequate timeframe to prepare and administer one dose of therapy. If claims history is available, verification is required for certain criteria as noted by **[verification in claims history required]**. For the dosing criteria, verification of the appropriate weight-based dosing is required by a Medical Director as noted by **[verification required]**. In the criteria for Casgevy, as appropriate, the symbol (†) is noted next to the specified gender. In this context, the specified gender is defined as follows: females/males are defined as individuals with the biological traits of a woman/man, regardless of the individual's gender identity or gender expression.

All reviews (approvals and denials) will be forwarded to the Medical Director for evaluation. Some clients have elected Embarc Benefit Protection. For these clients, the Medical Director will coordinate with eviCore to ensure the Embarc Benefit Protection portion of the review has been completed. If the Embarc Benefit Protection portion of the review has not been completed, the Medical Director will route to Embarc@eviCore.com prior to completing the review.

Documentation: Documentation is required for use of Casgevy as noted in the criteria as **[documentation required]**. Documentation may include, but is not limited to, chart notes, laboratory results, medical test results, claims records, prescription receipts, and/or other information.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Casgevy is recommended in those who meet one of the following criteria:

FDA-Approved Indications

1. **Sickle Cell Disease.** Approve a one-time (per lifetime) single dose if the patient meets ALL of the following (A, B, C, D, E, F, G, H, I, J, K, L, M, N, and O):

B) Patient is ≥ 12 years of age; AND

C) Patient has not received a gene therapy for sickle cell disease in the past **[verification in claims history required]**; AND

Note: If no claim for Casgevy or Lyfgenia (lovotibeglogene autotemcel intravenous infusion) is present (or if claims history is not available), the prescribing physician confirms that the patient has not previously received Casgevy or Lyfgenia.

D) According to the prescribing physician, a hematopoietic stem cell transplantation is appropriate for the patient; AND

E) Patient meets ONE of the following (i or ii):

i. Patient does not have a Human Leukocyte Antigen (HLA)-matched donor; OR

ii. Patient has an HLA-matched donor, but the individual is not able or is not willing to donate; AND

F) Genetic testing **[documentation required]** indicates the patient has ONE of the following sickle cell disease genotypes (i, ii, or iii):

i. β^S/β^S genotype; OR

ii. β^S/β^0 genotype; OR

iii. β^S/β^+ genotype; AND

Note: Other genotypes will be reviewed by the Medical Director on a case-by-case basis.

G) Patient has tried at least ONE pharmacologic treatment for sickle cell disease **[documentation required]**; AND

Note: Examples of pharmacologic treatment for sickle cell disease include hydroxyurea, L-glutamine, Adakveo (crizanlizumab-tmca intravenous infusion), and Oxbryta (voxelotor tablets and tablets for oral suspension).

H) While receiving appropriate standard treatment for sickle cell disease, patient had at least four severe vaso-occlusive crises or events in the previous 2 years, as defined by the following (i, ii, iii, iv, or v):

i. An episode of acute pain that resulted in a visit to a medical facility which required administration of at least ONE of the following (a or b) **[documentation required]**:

a) Intravenous opioid; OR

b) Intravenous nonsteroidal anti-inflammatory drug; OR

ii. Acute chest syndrome **[documentation required]**; OR

Note: Acute chest syndrome is defined by the presence of a new pulmonary infiltrate associated with pneumonia-like symptoms (e.g., chest pain, fever [$> 99.5^\circ\text{F}$], tachypnea, wheezing or cough, or findings upon lung auscultation).

iii. Acute hepatic sequestration **[documentation required]**; OR

Note: Acute hepatic sequestration is defined by a sudden increase in liver size associated with pain in the right upper quadrant, abnormal results of liver function test not due to biliary tract disease, and the reduction of hemoglobin concentration by ≥ 2 g/dL below the baseline value.

iv. Acute splenic sequestration **[documentation required]**; OR

Note: Acute splenic sequestration is defined by an enlarged spleen, left upper quadrant pain, and an acute decrease in hemoglobin concentration of ≥ 2 g/dL below the baseline value.

v. Acute priapism lasting > 2 hours and requiring a visit to a medical facility **[documentation required]**; AND

- I)** Patient does **not** have the following (i, ii, iii, and iv):
- i.** Clinically significant and active bacterial, viral, fungal, or parasitic infection; AND
 - ii.** Advanced liver disease **[documentation required]**; AND
Note: Examples of advanced liver disease include alanine transaminase > 3 times upper limit of normal; direct bilirubin value > 2.5 times upper limit of normal; baseline prothrombin time (international normalized ratio [INR]) > 1.5 times upper limit of normal; cirrhosis; bridging fibrosis; or active hepatitis.
 - iii.** Severe cerebral vasculopathy as defined by history of untreated Moyamoya disease or presence of Moyamoya disease that puts the patient at risk of bleeding, per the prescribing physician; AND
 - iv.** Prior or current malignancy, myeloproliferative disorder, or significant immunodeficiency disorder; AND
- I)** According to the prescribing physician, patient will have been discontinued from the following medications (for the duration noted) [i and ii]:
- i.** Disease-modifying therapies for sickle cell disease for at least 2 months before the planned start of mobilization and conditioning; AND
Note: Examples of disease-modifying therapies for sickle cell disease include hydroxyurea, Adakveo, L-glutamine, and Oxbryta.
 - ii.** Iron chelation therapy for at least 7 days prior to myeloablative conditioning; AND
Note: Examples of iron chelators used for this condition include deferoxamine injection, deferasiprone tablets or solution, and deferasirox tablets.
- J)** According to the prescribing physician, patient meets ALL of the following (i, ii, iii, and iv):
- i.** Patient will undergo mobilization, apheresis, and myeloablative conditioning; AND
 - ii.** A hematopoietic stem cell mobilizer will be utilized for mobilization; AND
Note: Mozobil (plerixafor subcutaneous injection) is an example of a hematopoietic stem cell mobilizer.
 - iii.** Busulfan will be used for myeloablative conditioning; AND
 - iv.** Sickle hemoglobin level will be < 30% of total hemoglobin with total hemoglobin concentration ≤ 11 g/dL at BOTH of the following timepoints (a and b):
 - a)** Prior to planned start of mobilization; AND
 - b)** Until initiation of myeloablative conditioning; AND
- K)** Prior to collection of cells for manufacturing, cellular screening is negative for ALL of the following (i, ii, iii, and iv):
- i.** Human immunodeficiency virus-1 and -2 **[documentation required]**; AND
 - ii.** Hepatitis B virus **[documentation required]**; AND
Note: A patient who has been vaccinated against hepatitis B virus (HBV) [HBV surface antibody-positive] who is negative for other markers of prior HBV infection (e.g., negative for HBV core antibody) is eligible; a patient with past exposure to HBV is also eligible as long as patient is negative for HBV DNA.
 - iii.** Hepatitis C virus **[documentation required]**; AND
 - iv.** Human T-lymphotrophic virus-1 and -2 **[documentation required]**; AND
- L)** According to the prescribing physician, patient meets ONE of the following (i or ii):
- i.** A female† of reproductive potential meets BOTH of the following (a and b):
 - a)** A negative serum pregnancy test will be confirmed prior to the start of each mobilization cycle and re-confirmed prior to myeloablative conditioning; AND
 - b)** Patient will use an effective method of contraception from the start of mobilization through at least 6 months after administration of Casgevy; OR
 - ii.** A male† of reproductive potential will use an effective method of contraception from the start of mobilization through at least 6 months after administration of Casgevy; AND
- M)** The medication is prescribed by a hematologist or a stem cell transplant physician; AND

- N) Current patient body weight has been obtained within 30 days **[documentation required]**; AND
- O) If criteria A through N are met, approve one dose of Casgevy by intravenous infusion to provide a one-time (per lifetime) single dose, which contains a minimum of 3×10^6 CD34+ cells/kg of body weight **[verification required]**.

Note: A single dose of Casgevy is composed of one or more vial(s).

† Refer to the Policy Statement.

2. Transfusion-Dependent Beta-Thalassemia. Approve a one-time (per lifetime) single dose if the patient meets ALL of the following (A, B, C, D, E, F, G, H, I, J, K, L, M, N, O, and P):

- A) Patient is ≥ 12 years of age; AND
- B) Patient has not received a gene therapy for beta-thalassemia in the past **[verification in claims history required]**; AND

Note: If no claim for Casgevy or Zynteglo (betibeglogene autotemcel intravenous infusion) is present (or if claims is not available), the prescribing physician confirms that the patient has not previously received Casgevy or Zynteglo.

- C) According to the prescribing physician, a hematopoietic stem cell transplantation is appropriate for the patient; AND
- D) Patient meets ONE of the following (i or ii):
- Patient does not have a Human Leukocyte Antigen (HLA)-matched donor; OR
 - Patient has a HLA-matched donor, but the individual is not able or is not willing to donate; AND
- E) Patient has ONE of the following genotypes as confirmed by genetic testing (i or ii):
- Non- β^0/β^0 genotype **[documentation required]**; OR
Note: Examples include β^0/β^+ , β^E/β^0 , and β^+/ β^+ .
 - β^0/β^0 genotypes **[documentation required]**; AND
Note: Other examples include $\beta^0/\beta^{+(IVS-I-110)}$ and $\beta^{+(IVS-I-110)}/\beta^{+(IVS-I-110)}$.
- F) Patient is transfusion-dependent, as defined by meeting ONE of the following (i or ii):
- Receipt of transfusions of ≥ 100 mL of packed red blood cells per kg of body weight per year in the previous 2 years **[documentation required]**; OR
 - Receipt of transfusions of ≥ 10 units of packed red blood cells per year in the previous 2 years **[documentation required]**; AND
- G) Patient meets BOTH of the following (i and ii):
- Patient has been evaluated for the presence of severe iron overload **[documentation required]**; AND
 - Patient does not have evidence of severe iron overload; AND
Note: Examples include abnormal myocardial iron results (a T2*-weighted magnetic resonance imaging measurement of myocardial iron of less than 10 msec); high liver iron concentration (≥ 15 mg/g); liver biopsy results suggest abnormalities; or clinical evidence of organ damage (e.g., endocrine comorbidities).
- H) Patient does not currently have an active bacterial, viral, fungal, or parasitic infection; AND
- I) Patient does not have the following (i and ii):
- Prior or current malignancy, myeloproliferative disorder, or significant immunodeficiency disorder; AND
Note: This does not include adequately treated cone biopsied in situ carcinoma of the cervix uteri and basal or squamous cell carcinoma of the skin.
 - Advanced liver disease **[documentation required]**; AND
Note: Examples include alanine transaminase or aspartate transaminase greater than three times upper limit of normal, direct bilirubin value greater than three times upper limit of normal, active hepatitis, extensive bridging fibrosis, or cirrhosis.

- J)** According to the prescribing physician, patient will have been discontinued from iron chelation therapy for at least 7 days prior to myeloablative conditioning; AND
Note: Examples of iron chelators used for this condition include deferoxamine injection, deferiprone tablets or solution, and deferasirox tablets.
- K)** According to the prescribing physician, patient meets ALL of the following (i, ii, iii, and iv):
- i.** Patient will undergo mobilization, apheresis, and myeloablative conditioning; AND
 - ii.** A granulocyte-colony stimulating factor product and a hematopoietic stem cell mobilizer will be utilized for mobilization; AND
Note: Filgrastim products are examples of a granulocyte-colony stimulating factor therapy and Mozobil (plerixafor subcutaneous injection) is an example of a hematopoietic stem cell mobilizer.
 - iii.** Busulfan will be used for myeloablative conditioning; AND
 - iv.** Total hemoglobin level is ≥ 11 g/dL at BOTH of the following timepoints (a and b):
 - a)** Prior to mobilization; AND
 - b)** Prior to myeloablative conditioning; AND
- L)** Prior to collection of cells for manufacturing, cellular screening is negative for ALL of the following (i, ii, iii, and iv):
- i.** Human immunodeficiency virus-1 and -2 **[documentation required]**; AND
 - ii.** Hepatitis B virus **[documentation required]**; AND
 - iii.** Hepatitis C virus **[documentation required]**; AND
 - iv.** Human T-lymphotropic virus-1 and -2 **[documentation required]**; AND
- M)** According to the prescribing physician, patient meets ONE of the following (i or ii):
- i.** A female† of reproductive potential meets BOTH of the following (a and b):
 - a)** A negative serum pregnancy test will be confirmed prior to the start of each mobilization cycle and re-confirmed prior to myeloablative conditioning; AND
 - b)** Patient will use an effective method of contraception from the start of mobilization through at least 6 months after administration of Casgevy; OR
 - ii.** A male† of reproductive potential will use an effective method of contraception from the start of mobilization through at least 6 months after administration of Casgevy; AND
- N)** The medication is prescribed by a hematologist or a stem cell transplant physician; AND
- O)** Current patient body weight has been obtained within 30 days **[documentation required]**; AND
- P)** If criteria A through O are met, approve one dose of Casgevy by intravenous infusion to provide a one-time (per lifetime) single dose, which contains a minimum of 3×10^6 CD34+ cells/kg of body weight **[verification required]**.
Note: A single dose of Casgevy is composed of one or more vial(s).

† Refer to the Policy Statement.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Casgevy is not recommended in the following situations:

128. Prior Hematopoietic Stem Cell Transplantation.

Note: Prescribing physician must confirm that the patient has not received a prior hematopoietic stem cell transplantation.

Casgevy has not been studied in a patient who has received a prior allogeneic or autologous hematopoietic stem cell transplant. Treatment with Casgevy is not recommended.

129. Prior Receipt of Gene Therapy. Casgevy has not been studied in a patient who has received prior gene therapy such as Lyfgenia® (lovotibeglogene autotemcel intravenous infusion) and Zynteglo® (betibeglogene autotemcel intravenous infusion). Treatment with Casgevy is not recommended.

130. Concurrent Use with Reblozyl® (luspatercept-aamt subcutaneous injection). Reblozyl was not utilized with Casgevy in the pivotal trial assessing the efficacy of Casgevy in patients with transfusion-dependent beta-thalassemia.

131. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hematology – Gene Therapy – Lyfgenia Prior Authorization Policy

- Lyfgenia® (lovotibeglogene autotemcel intravenous infusion – bluebird bio)

REVIEW DATE: 01/31/2024; selected revision 03/20/2024

OVERVIEW

Lyfgenia, an autologous hematopoietic stem cell-based gene therapy, is indicated for the treatment of **sickle cell disease** in patients ≥ 12 years of age with a history of vaso-occlusive events (VOEs).¹ Limitation of Use. Following treatment with Lyfgenia, patients with α -thalassemia trait ($-\alpha 3.7/-\alpha 3.7$) may experience anemia with erythroid dysplasia that may require chronic red blood cell (RBC) transfusions. Lyfgenia has not been studied in patients with more than two α -globin gene deletions.

Lyfgenia is given as a single dose (once per lifetime), which contains a minimum of 3×10^6 cluster of differentiation 34+ (CD34+) cells/kg of body weight. Lyfgenia is given as an intravenous (IV) infusion. The manufacturing time for Lyfgenia takes between 10 to 15 weeks. However, the entire process can take 6 months or longer as patients need to undergo mobilization and apheresis procedures and myeloablative conditioning prior to Lyfgenia infusion.

Lyfgenia is prepared with the patient's own hematopoietic stem cells, which are collected via apheresis procedure(s).^{1,2} The CD34+ cells collected from the patient are transduced *ex vivo* with BB305 lentiviral vector (BB305 LVV). The BB305 LVV encodes a modified β -globin gene, which ultimately results in the production of HbA^{T87Q}, a modified adult hemoglobin (HbA). HbA^{T87Q} maintains 99.9% identity to HbA and has a similar oxygen-binding affinity as that of HbA; the difference is that HbA^{T87Q} is designed to inhibit polymerization of the sickle hemoglobin.

Disease Overview

Sickle cell disease is a group of inherited RBC disorders characterized by the presence of a mutated hemoglobin (Hb) subunit beta gene.³⁻⁵ Healthy RBCs are round and contain Hb. In contrast, in a patient with sickle cell disease, RBCs are sickle-shaped and die early, resulting in a constant shortage of RBCs. Furthermore, the sickle-shaped RBCs aggregate in the bloodstream, causing vaso-occlusion, which deprive downstream tissues of nutrients and oxygen, resulting in tissue ischemia, organ damage, and hemolysis (which leads to anemia). In the US, approximately 100,000 persons have the condition and it is estimated 20,000 patients have severe sickle cell disease.^{3,6}

Patients with severe sickle cell disease have one of the following genotypes: β^S/β^S , β^S/β^0 , β^S/β^+ .³⁻⁵ These patients have recurrent vaso-occlusive crises/VOEs, while receiving appropriate supportive care (e.g., pain management, hydroxyurea). Management of sickle cell disease focuses on preventing and treating pain episodes and other complications; symptomatic treatment includes use of analgesics, fluids (hydration), oxygen supplementation, and blood transfusion. Allogeneic hematopoietic stem cell transplantation (HSCT) requires a stem cell donor, typically a human leukocyte antigen (HLA)-matched donor; less than 20% of patients with sickle cell disease have a suitable donor.⁶ Pharmacologic treatments for sickle cell disease include Adakveo® (crizanlizumab-tmca IV infusion), Endari® (L-glutamine oral powder), hydroxyurea, and Oxbryta® (voxelotor tablets and tablets for oral suspension).⁷⁻¹¹

Clinical Efficacy

The efficacy of Lyfgenia was studied in a single-arm, 24-month, open-label, multicenter Phase I/II study involving adolescents and adults with sickle cell disease.^{1,2} In total, there were 36 patients who underwent apheresis after mobilization with plerixafor and received myeloablative conditioning with busulfan and Lyfgenia infusion.¹ Of the 36 patients, 32 patients met the criteria for the “transplant population for VOE efficacy outcomes”, which included patients who met the VOE requirement; this population was used to analyze the efficacy endpoints. Patients were eligible to enroll if they had one of the following sickle cell disease genotypes: β^S/β^S , β^S/β^0 , or β^S/β^+ . However, all patients had the β^S/β^S genotype. In addition, the patients had at least four (protocol-defined) severe VOEs in the 24 months before enrollment and had to have failed hydroxyurea treatment or have intolerance to hydroxyurea. A VOE was defined as any of the following events requiring evaluation at a medical facility: an episode of acute pain with no medically determined cause other than vaso-occlusion and lasting > 2 hours; acute chest syndrome; acute hepatic sequestration; and acute splenic sequestration. Severe VOEs were defined as either a VOE requiring a hospitalization or multiple visits to an emergency department/urgent care over 72 hours and requiring IV medications at each visit OR priapism requiring any level of medical attention. Key exclusion criteria were patients with the following: clinically significant and active bacterial, viral, fungal, or parasitic infection; advanced liver disease; history or presence of Moyamoya disease; and prior or current malignancy or myeloproliferative disorder or significant immunodeficiency disorder. The median age of the patients was 25 years; 25% of the patients were adolescents (≥ 12 years to < 18 years of age). The primary efficacy endpoint was complete resolution of severe VOEs; the investigators also reported complete resolution of VOEs. Both outcomes were assessed between 6 and 18 months after Lyfgenia infusion. In total, 94% of patients (n = 30/32) had complete resolution of severe VOEs and 88% of patients (n = 28/32) had complete resolution of VOEs.

Guidelines

Sickle cell disease guidelines have not incorporated gene therapies following their FDA approval. The American Society of Hematology (ASH) released evidence-based recommendations for stem cell transplantation for patients with sickle cell disease in 2021.¹² ASH notes that it is unclear how gene therapies will affect sickle cell disease outcomes, including organ complications and if broader access to curative therapy will alter the trajectory of sickle cell disease outcomes. ASH notes that while success rates after allogeneic HSCT are increasing, survival rates in patients receiving disease-modifying medications (e.g., hydroxyurea, L-glutamine, Adakveo, Oxbryta) and supportive care are also improving. More than 90% of patients who have undergone HSCT (predominantly using HLA-identical family donors) have been cured of sickle cell disease, as reported in short-term follow-up. Allogeneic HSCT is an established therapeutic option for patients with sickle cell disease with a clinical indication and an HLA-identical family donor. However, for the majority of patients, there are no suitable donors.

Safety

Lyfgenia has a Boxed Warning regarding hematologic malignancy.¹ At the time of initial product approval, two patients treated with an earlier version of Lyfgenia using a different manufacturing process and transplant procedure developed acute myeloid leukemia and one patient with an α -thalassemia trait was diagnosed with myelodysplastic syndrome. Patients should be monitored for evidence of malignancy through complete blood counts at least every 6 months and through integration site analysis at Months 6, 12, and as warranted.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Lyfgenia. Approval is recommended for those who meet the Criteria for the listed indication. Because of the specialized skills required for evaluation and diagnosis of patients treated with Lyfgenia as well as the specialized training required for administration of Lyfgenia, approval requires Lyfgenia to be prescribed by a physician who specializes in the condition being treated. All approvals are provided for one-time (per lifetime) as a single dose. The approval duration is 1 year to allow for an adequate time frame to prepare and administer one dose of therapy. If claims history is available, verification is required for certain criteria as noted by **[verification in claims history required]**. For the dosing criteria, verification of the appropriate weight-based dosing is required by a Medical Director as noted by **[verification required]**. In the criteria for Lyfgenia, as appropriate, the symbol (†) is noted next to the specified gender. In this context, the specified gender is defined as follows: females/males are defined as individuals with the biological traits of a woman/man, regardless of the individual's gender identity or gender expression.

All reviews (approvals and denials) will be forwarded to the Medical Director for evaluation. Some clients have elected Embarc Benefit Protection. For these clients, the Medical Director will coordinate with eviCore to ensure the Embarc Benefit Protection portion of the review has been completed. If the Embarc Benefit Protection portion of the review has not been completed, the Medical Director will route to Embarc@eviCore.com prior to completing the review.

Documentation: Documentation is required for use of Lyfgenia as noted in the criteria as **[documentation required]**. Documentation may include, but is not limited to, chart notes, laboratory results, medical test results, claims records, prescription receipts, and/or other information.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Lyfgenia is recommended in those who meet the following criteria:

FDA-Approved Indication

1. **Sickle Cell Disease.** Approve a one-time (per lifetime) single dose if the patient meets ALL of the following (A, B, C, D, E, F, G, H, I, J, K, L, M, N, and O):
 - A) Patient is ≥ 12 years of age; AND
 - B) Patient has not received a gene therapy for sickle cell disease in the past **[verification in claims history required]**; AND
Note: If no claim for Lyfgenia or Casgevy (exagamglogene autotemcel intravenous infusion) is present (or if claims history is not available), the prescribing physician confirms that the patient has not previously received Lyfgenia or Casgevy.
 - C) According to the prescribing physician, a hematopoietic stem cell transplantation is appropriate for the patient; AND
 - D) Patient meets ONE of the following (i or ii):
 - i. Patient does not have a Human Leukocyte Antigen (HLA)-matched donor; OR
 - ii. Patient has an HLA-matched donor, but the individual is not able or is not willing to donate; AND
 - E) Genetic testing **[documentation required]** indicates the patient has ONE of the following sickle cell disease genotypes (i, ii, or iii):
 - i. β^S/β^S genotype; OR
 - ii. β^S/β^0 genotype; OR

iii. β^S/β^+ genotype; AND

Note: Other genotypes will be reviewed by the Medical Director on a case-by-case basis.

- F) Patient has tried at least ONE pharmacologic treatment for sickle cell disease **[documentation required]**; AND

Note: Examples of pharmacologic treatment for sickle cell disease include hydroxyurea, L-glutamine, Adakveo (crizanlizumab-tmca intravenous infusion), and Oxbryta (voxelotor tablets and tablets for oral suspension).

- G) While receiving appropriate standard treatment for sickle cell disease, patient had at least four severe vaso-occlusive crises or events in the previous 2 years, as defined by the following (i, ii, iii, iv, or v):

ii. An episode of acute pain that resulted in a visit to a medical facility which required administration of at least ONE of the following (a or b) **[documentation required]**:

i. Intravenous opioid; OR

ii. Intravenous nonsteroidal anti-inflammatory drug; OR

iii. Acute chest syndrome **[documentation required]**; OR

Note: Acute chest syndrome is defined by the presence of a new pulmonary infiltrate associated with pneumonia-like symptoms (e.g., chest pain, fever [$> 99.5^\circ\text{F}$], tachypnea, wheezing or cough, or findings upon lung auscultation).

iv. Acute hepatic sequestration **[documentation required]**; OR

Note: Acute hepatic sequestration is defined by a sudden increase in liver size associated with pain in the right upper quadrant, abnormal results of liver function test not due to biliary tract disease, and the reduction of hemoglobin concentration by ≥ 2 g/dL below the baseline value.

v. Acute splenic sequestration **[documentation required]**; OR

Note: Acute splenic sequestration is defined by an enlarged spleen, left upper quadrant pain, and an acute decrease in hemoglobin concentration of ≥ 2 g/dL below the baseline value.

vi. Acute priapism lasting > 2 hours and requiring a visit to a medical facility **[documentation required]**; AND

- H) Patient does not have the following (i, ii, iii, iv, and v):

i. More than two α -globin gene deletions **[documentation required]**; AND

ii. Clinically significant and active bacterial, viral, fungal, or parasitic infection; AND

iii. Advanced liver disease **[documentation required]**; AND

Note: Examples of advanced liver disease include alanine transaminase > 3 times upper limit of normal; direct bilirubin value > 2.5 times upper limit of normal; baseline prothrombin time (international normalized ratio [INR]) > 1.5 times upper limit of normal; cirrhosis; bridging fibrosis; or active hepatitis.

iv. Severe cerebral vasculopathy as defined by of untreated Moyamoya disease or presence of Moyamoya disease that puts the patient at risk of bleeding, per the prescribing physician; AND

v. Prior or current malignancy or myeloproliferative disorder or significant immunodeficiency disorder; AND

- I) According to the prescribing physician, patient will have been discontinued from the following medications (for the duration noted) prior to mobilization (i, ii, iii, and iv):

i. Disease-modifying therapies for sickle cell disease for at least 2 months; AND

Note: Examples of disease-modifying therapies for sickle cell disease include hydroxyurea, Adakveo, L-glutamine, and Oxbryta.

ii. Erythropoietin for at least 2 months; AND

iii. Iron chelation therapy for at least 7 days; AND

Note: Examples of iron chelators used for this condition include deferoxamine injection, deferiprone tablets or solution, and deferasirox tablets.

iv. Anti-retrovirals (prophylactic for human immunodeficiency virus [HIV]) for at least 1 month; AND

Note: Examples of anti-retrovirals for HIV include abacavir, emtricitabine, lamivudine, and zidovudine.

- J)** According to the prescribing physician, patient meets ALL of the following (i, ii, iii, and iv):
- i.** Patient will undergo mobilization, apheresis, and myeloablative conditioning; AND
 - ii.** A hematopoietic stem cell mobilizer will be utilized for mobilization; AND
Note: Mozobil (plerixafor subcutaneous injection) is an example of a hematopoietic stem cell mobilizer.
 - iii.** Busulfan will be used for myeloablative conditioning; AND
 - iv.** Sickle hemoglobin level will be < 30% of total hemoglobin with total hemoglobin concentration ≤ 11 g/dL at BOTH of the following timepoints (a and b):
 - a)** Prior to planned start of mobilization; AND
 - b)** Until initiation of myeloablative conditioning; AND
- K)** Prior to collection of cells for manufacturing, cellular screening is negative for ALL of the following (i, ii, iii, and iv):
- i.** Human immunodeficiency virus-1 and -2 **[documentation required]**; AND
 - ii.** Hepatitis B virus **[documentation required]**; AND
Note: A patient who has been vaccinated against hepatitis B virus (HBV) [HBV surface antibody-positive] who is negative for other markers of prior HBV infection (e.g., negative for HBV core antibody) is eligible; a patient with past exposure to HBV is also eligible as long as patient is negative for HBV DNA.
 - iii.** Hepatitis C virus **[documentation required]**; AND
 - iv.** Human T-lymphotrophic virus-1 and -2 **[documentation required]**; AND
- L)** According to the prescribing physician, patient meets ONE of the following (i or ii):
- i.** A female† of reproductive potential meets BOTH of the following (a and b):
 - a)** A negative serum pregnancy test will be confirmed prior to the start of each mobilization cycle and re-confirmed prior to myeloablative conditioning; AND
 - b)** Patient will use an effective method of contraception from the start of mobilization through at least 6 months after administration of Lyfgenia; OR
 - ii.** A male† of reproductive potential will use an effective method of contraception from the start of mobilization through at least 6 months after administration of Lyfgenia; AND
- M)** The medication is prescribed by a hematologist or a stem cell transplant physician; AND
- N)** Current patient body weight has been obtained within 30 days **[documentation required]**; AND
- O)** If criteria A through N are met, approve one dose of Lyfgenia by intravenous infusion to provide a one-time (per lifetime) single dose, which contains a minimum of 3×10^6 CD34+ cells/kg of body weight **[verification required]**.
Note: A single dose of Lyfgenia is composed of one or more infusion bag(s).

† Refer to the Policy Statement.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Lyfgenia is not recommended in the following situations:

132. Prior Hematopoietic Stem Cell Transplantation.

Note: Prescribing physician must confirm that the patient has not received a prior hematopoietic stem cell transplantation.

Lyfgenia has not been studied in a patient who has received a prior allogeneic or autologous hematopoietic stem cell transplant. Treatment with Lyfgenia is not recommended.

133. Prior Receipt of Gene Therapy.

Lyfgenia has not been studied in a patient who has received prior gene therapy such as Casgevy™ (exagamglogene autotemcel intravenous infusion). Treatment with Lyfgenia is not recommended.

134. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hematology – Gene Therapy – Zynteglo Prior Authorization Policy

- Zynteglo™ (betibeglogene autotemcel intravenous infusion – Bluebird Bio)

REVIEW DATE: 03/20/2024; selected revision 09/25/2024

OVERVIEW

Zynteglo, an autologous hematopoietic stem cell-based gene therapy, is indicated for the treatment of beta-thalassemia in adult and pediatric patients who require regular red blood cell (RBC) transfusions.¹ The efficacy and safety of Zynteglo in children < 4 years of age have not been established; no data are available in this population. Casgevy™ (exagamglogene autotemcel intravenous infusion), an autologous hematopoietic stem cell-based gene therapy, is indicated for the treatment of transfusion-dependent beta-thalassemia in patients ≥ 12 years of age.⁵ Casgevy is also indicated for the treatment of sickle cell disease in patients ≥ 12 years of age with recurrent vaso-occlusive crises. Casgevy is also given as a one-time (per lifetime) single dose.

Zynteglo is given as a one-time (per lifetime) single dose which contains a minimum of 5.0×10^6 CD34+ cells/kg of body weight. Zynteglo is given as an intravenous infusion. The median dose of Zynteglo in the pivotal trials was 9.4×10^6 CD34+ cells/kg. The manufacturing time (which includes quality control) can take up to 6 months. Patients need to undergo mobilization and apheresis procedures, as well as myeloablative conditioning prior to Zynteglo infusion.

Zynteglo is prepared from the patient's own hematopoietic stem cells, which are obtained via apheresis procedure(s). Zynteglo is a β^{A-T87Q} -globin gene therapy comprised of autologous CD34+ cells, containing hematopoietic stem cells transduced with BB305 lentiviral vector (LVV) encoding β^{A-T87Q} -globin. Zynteglo adds functional copies of a modified form of the β -globin gene (β^{A-T87Q} -globin gene) into individual hematopoietic stem cells.

Disease Overview

The condition of beta-thalassemia is a group of recessively inherited blood disorders caused by β -globin gene mutations that either reflect a reduced (β^+) or relative lack (β^0) of production of functional β -globin.² The attenuated or lack of hemoglobin (Hb) results in chronic anemia of varying degrees of severity and insufficient delivery of oxygen to the body. Those with severe anemia may require lifelong RBC transfusions and regular iron chelation to prevent iron overload. The extremely low Hb levels can lead to many types of symptoms and health-related issues (e.g., dizziness, weakness, fatigue, increased cardiac effort, tachycardia, poor growth) or ineffective erythropoiesis (e.g., bone changes, massive splenomegaly). An estimated 3,000 patients in the US have beta-thalassemia and slightly less than one-half of the patients are dependent on RBC transfusions.

Clinical Efficacy

The efficacy of Zynteglo was evaluated in two ongoing, open-label, 2-year, single-arm, Phase III trials that involved patients ≤ 50 years of age with transfusion-dependent beta-thalassemia (NORTHSTAR-2 and NORTHSTAR-3) who received one dose of Zynteglo.^{1,3} All patients underwent mobilization of stem cells (with granulocyte colony-stimulating factor and Mozobil® [plerixafor subcutaneous injection]) and pre-treatment myeloablative conditioning with busulfan prior to treatment with Zynteglo. NORTHSTAR-2 (n = 23) involved patients who had a non- β^0/β^0 genotype. NORTHSTAR-3 (n = 18) involved patients who had a β^0/β^0 or non- β^0/β^0 genotype. In NORTHSTAR-2, 91% of patients obtained transfusion independence,

03/20/2024

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

the primary endpoint. Among the patients who obtained transfusion independence, the median weighted average Hb during transfusion independence was 11.8 g/dL.¹ In NORTHSTAR-3, transfusion independence was achieved by 86% of patients. Among the patients who obtained transfusion independence, the median weighted average Hb during transfusion independence was 10.2 g/dL. The median time for the last RBC transfusion prior to transfusion independence after administration of Zynteglo was slightly under 1 month in both trials. In total, 29 patients from NORTHSTAR-2 and NORTHSTAR-3 enrolled in a long-term extension. Data suggest durable results regarding transfusion independence as these two studies have had follow up for over 24 months.

Guidelines

Guidelines have not addressed Zynteglo or Casgevy post approval in the US. In 2021, the Thalassaemia International Federation published guidelines for the management of transfusion-dependent thalassemia.⁴

- **Chelation therapy** was cited as an effective treatment modality in improving survival, decreasing the risk of heart failure, and decreasing morbidities from transfusion-induced iron overload. The optimal chelation regimen should be individualized and will vary among patients and their clinical status.
- **Allogeneic hematopoietic stem cell transplant (HSCT)** should be offered to patients with beta-thalassemia at an early age, before complications due to iron overload have developed if a human leukocyte antigen (HLA) identical sibling is available. In some clinical circumstances, a matched unrelated donor can be adequate.
- **Reblozyl**[®] (luspatercept-aamt subcutaneous injection), an erythroid maturation agent, can be considered for patients ≥ 18 years of age who require regular RBC transfusions.
- **Zynteglo**, when available, may be an option for selected patients. Examples include young patients (12 to 17 years of age) with a β^+ genotype who do not have an HLA-compatible sibling donor. Also, Zynteglo can be considered in patients 17 to 55 years of age with a β^+ genotype who do not have severe comorbidities and are at risk or ineligible to undergo allogeneic HSCT but can otherwise undergo an autologous gene therapy procedure with an acceptable risk.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Zynteglo. Approval is recommended for those who meet the Criteria for the listed indication. Because of the specialized skills required for evaluation and diagnosis of patients treated with Zynteglo as well as the specialized training required for administration of Zynteglo, approval requires Zynteglo to be prescribed by a physician who specializes in the condition being treated. All approvals are provided for one-time (per lifetime) as a single dose. The approval duration is 1 year to allow for an adequate timeframe to prepare and administer one dose of therapy. If claims history is available, verification is required for certain criteria as noted by **[verification in claims history required]**. For the dosing criteria, verification of the appropriate weight-based dosing is required by the Medical Director as noted by **[verification required]**. In the criteria for Zynteglo, as appropriate, the symbol (†) is noted next to the specified gender. In this context, the specified gender is defined as follows: females/males are defined as individuals with the biological traits of a woman/man, regardless of the individual's gender identity or gender expression.

All reviews (approvals and denials) will be forwarded to the Medical Director for evaluation. Some clients have elected Embarc Benefit Protection. For these clients, the Medical Director will coordinate with eviCore to ensure the Embarc Benefit Protection portion of the review has been completed. If the Embarc Benefit Protection portion of the review has not been completed, the Medical Director will route to Embarc@eviCore.com prior to completing the review.

Documentation: Documentation is required for use of Zynteglo as noted in the criteria as **[documentation required]**. Documentation may include, but is not limited to, chart notes, laboratory results, medical test results, claims records, prescription receipts, and/or other information.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Zynteglo is recommended in those who meet the following criteria:

FDA-Approved Indication

16. Transfusion-Dependent Beta-Thalassemia. Approve a one-time (per lifetime) single dose if the patient meets ALL of the following (A, B, C, D, E, F, G, H, I, J, K, L, M, N, O, and P).

A) Patient is ≥ 4 years of age; AND

B) Patient has not received a gene therapy for beta-thalassemia in the past **[verification in claims history required]**; AND

Note: If no claim for Zynteglo or Casgevy (exagamglogene autotemcel intravenous infusion) is present (or if claims is not available), the prescribing physician confirms that the patient has not previously received Zynteglo or Casgevy.

C) According to the prescribing physician, a hematopoietic stem cell transplantation is appropriate for the patient; AND

D) Patient meets ONE of the following (i or ii):

i. Patient does not have a Human Leukocyte Antigen (HLA)-matched donor; OR

ii. Patient has an HLA-matched donor, but the individual is not able or is not willing to donate; AND

E) Patient has ONE of the following genotypes as confirmed by genetic testing (i or ii):

i. Non- β^0/β^0 genotype **[documentation required]**; OR

Note: Examples include β^0/β^+ , β^E/β^0 , and β^+/β^+ .

ii. β^0/β^0 genotypes **[documentation required]**; AND

Note: Other examples include $\beta^0/\beta^{+(IVS-I-110)}$ and $\beta^{+(IVS-I-110)}/\beta^{+(IVS-I-110)}$.

F) Patient is transfusion-dependent, as defined by meeting ONE of the following (i or ii):

i. Receipt of transfusions of ≥ 100 mL of packed red cells per kg of body weight per year in the previous 2 years **[documentation required]**; OR

ii. Receipt of transfusions eight or more times per year in the previous 2 years **[documentation required]**; AND

G) Patient meets BOTH of the following (i and ii):

i. Patient has been evaluated for the presence of severe iron overload **[documentation required]**; AND

ii. Patient does not have evidence of severe iron overload; AND

Note: Examples include abnormal myocardial iron results (a T2*-weighted magnetic resonance imaging measurement of myocardial iron of less than 10 msec), high liver iron concentration (≥ 15 mg/g), liver biopsy results suggest abnormalities, or clinical evidence of organ damage (e.g., endocrine comorbidities).

H) Patient does not currently have an active bacterial, viral, fungal, or parasitic infection; AND

I) Patient does not have any of the following (i and ii):

i. Prior or current malignancy, myeloproliferative disorder, or significant immunodeficiency disorder; AND

Note: This does not include adequately treated cone biopsied in situ carcinoma of the cervix uteri and basal or squamous cell carcinoma of the skin.

- ii. Advanced liver disease **[documentation required]**; AND
Note: Examples include alanine transaminase or aspartate transaminase greater than three times upper limit of normal, direct bilirubin value greater than three times upper limit of normal, active hepatitis, extensive bridging fibrosis, or cirrhosis.
- J) According to the prescribing physician, patient will have been discontinued from iron chelation therapy for at least 7 days prior to myeloablative conditioning; AND
Note: Examples of iron chelators used for this condition include deferoxamine injection, deferiprone tablets or solution, and deferasirox tablets.
- K) According to the prescribing physician, patient meets ALL of the following (i, ii, iii, and iv):
 - i. Patient will undergo mobilization, apheresis, and myeloablative conditioning; AND
 - ii. A granulocyte-colony stimulating factor product and a hematopoietic stem cell mobilizer will be utilized for mobilization; AND
Note: Filgrastim products are examples of a granulocyte-colony stimulating factor therapy and Mozobil (plerixafor subcutaneous injection) is an example of a hematopoietic stem cell mobilizer.
 - iii. Busulfan will be used for myeloablative conditioning; AND
 - iv. Total hemoglobin level is ≥ 11.0 g/dL at BOTH of the following timepoints (a and b):
 - a) Prior to mobilization; AND
 - b) Prior to myeloablative conditioning; AND
- L) Prior to collection of cells for manufacturing, cellular screening is negative for ALL the following (i, ii, iii, and iv):
 - i. Human immunodeficiency virus-1 and -2 **[documentation required]**; AND
 - ii. Hepatitis B virus **[documentation required]**; AND
 - iii. Hepatitis C virus **[documentation required]**; AND
 - iv. Human T-lymphotropic virus-1 and -2 **[documentation required]**; AND
- M) According to the prescribing physician, patient meets ONE of the following (i or ii):
 - i. A female[†] of reproductive potential meets BOTH of the following (a and b):
 - a) A negative serum pregnancy test will be confirmed prior to the start of mobilization and re-confirmed prior to myeloablative conditioning; AND
 - b) Patient will use an effective method of contraception from the start of mobilization through at least 6 months after administration of Zynteglo; OR
 - ii. A male[†] of reproductive potential will use an effective method of contraception from the start of mobilization through at least 6 months after administration of Zynteglo; AND
- N) The medication is prescribed by a hematologist or a stem cell transplant specialist physician; AND
- O) Current patient body weight has been obtained within 30 days **[documentation required]**; AND
- P) If criteria A through O are met, approve one dose of Zynteglo by intravenous infusion to provide a one-time (per lifetime) single dose which contains a minimum of 5.0×10^6 CD34+ cells/kg of body weight **[verification required]**.

[†] Refer to the Policy Statement.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Zynteglo is not recommended in the following situations:

135. Prior Hematopoietic Stem Cell Transplantation.

Note: Prescribing physician must confirm that the patient has not received a prior hematopoietic stem cell transplantation.

Zynteglo has not been studied in a patient who has received a prior allogeneic or autologous hematopoietic stem cell transplant. Treatment with Zynteglo is not recommended.

136. Prior Receipt of Gene Therapy. Prior receipt of gene therapy was a reason for patient exclusion in the two pivotal trials.

137. Concurrent Use with Reblozyl (luspatercept-aamt subcutaneous injection). Reblozyl was not utilized with Zynteglo in the pivotal trials assessing Zynteglo in patients with transfusion-dependent beta-thalassemia.

138. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hematology – Pyrukynd Prior Authorization Policy

- Pyrukynd® (mitapivat tablets – Agios)

REVIEW DATE: 02/28/2024

OVERVIEW

Pyrukynd, a pyruvate kinase activator, is indicated for the treatment of **hemolytic anemia due to pyruvate kinase deficiency** in adults.¹

It is recommended to discontinue Pyrukynd if no benefit has been observed by 24 weeks as evaluated by hemoglobin and hemolysis laboratory results and transfusion requirements.

Disease Overview

Pyruvate kinase deficiency is a rare (three to nine cases per one million people), autosomal recessive enzyme defect in red blood cells that is caused by mutations in the pyruvate kinase liver and red blood cell (*PKLR*) gene.^{2,3} These alterations result in a deficit of pyruvate kinase activity in red blood cells which leads to hemolytic anemia of varying severity.² Other complications include iron overload (and its sequelae), bilirubin gallstones, pulmonary hypertension, thrombosis, and extramedullary hematopoiesis. Commonly present are compound heterozygous mutations in the gene encoding the L and R isozymes of *PKLR* with more than 300 mutations noted; most patients have at least one missense mutation. More notable management strategies involve blood transfusions, splenectomy, and chelation therapy.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Pyrukynd. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Pyrukynd as well as the monitoring required for adverse events and long-term efficacy, approval requires Pyrukynd to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Documentation: Documentation is required for use of Pyrukynd as noted in the criteria as **[documentation required]**. Documentation may include, but is not limited to, chart notes, laboratory tests, claims records, and/or other information.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Pyrukynd is recommended in those who meet the following criteria:

FDA-Approved Indication

17. Hemolytic Anemia Due to Pyruvate Kinase Deficiency. Approve for the duration noted below if the patient meets ONE of the following (A or B):

A) Initial Therapy. Approve for 6 months if the patient meets the following (i, ii, iii, and iv):

02/28/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- i. Patient is ≥ 18 years of age; AND
 - ii. Patient meets both of the following (a and b):
 - a) Presence of at least two variant/mutant alleles in the pyruvate kinase liver and red blood cell (*PKLR*) gene **[documentation required]**; AND
 - b) At least one of the variant/mutant alleles was a missense variant **[documentation required]**; AND
 - iii. Patient meets one of the following (a or b):
 - a) Patient has a current hemoglobin level ≤ 10 g/dL; OR
 - b) Patient is currently receiving red blood cell transfusions regularly, defined as at least six transfusions within the last year; AND
 - iv. The medication is prescribed by or in consultation with a hematologist.
- B) Patient is Currently Receiving Pyrukynd.** Approve for 1 year if the patient meets the following (i, ii, iii, and iv):
- i. Patient is ≥ 18 years of age; AND
 - ii. Patient meets both of the following (a and b):
 - a) Presence of at least two variant/mutant alleles in the pyruvate kinase liver and red blood cell (*PKLR*) gene **[documentation required]**; AND
 - b) At least one of the variant/mutant alleles was a missense variant **[documentation required]**; AND
 - iii. According to the prescriber, the patient has experienced a benefit from therapy based one of the following (a, b, or c):
 - a) Increase in or maintenance of hemoglobin levels; OR
 - b) Improvement in or maintenance of hemolysis laboratory parameters; OR
 - Note: Examples of laboratory parameters that are markers of hemolysis include indirect bilirubin, lactate dehydrogenase, and haptoglobin.
 - c) Decrease in or maintenance of transfusion requirements; AND
 - iv. The medication is prescribed by or in consultation with a hematologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Pyrukynd is not recommended in the following situations:

- 139. Patient with Pyruvate Kinase Deficiency Homozygous for the c.1436G>A (p.R479H) Variant/Mutation in the Pyruvate Kinase Liver and Red Blood Cell (*PKLR*) Gene.** Such patients were excluded from the pivotal studies investigating Pyrukynd in patients with pyruvate kinase deficiency because they did not achieve a hemoglobin response in the dose-ranging study.¹
- 140. Patient with Pyruvate Kinase Deficiency with Two Non-Missense Variants/Mutations (without the presence of another missense variant/mutation) in the Pyruvate Kinase Liver and Red Blood Cell (*PKLR*) Gene.** Such patients were excluded from the pivotal studies investigating Pyrukynd because they did not achieve a hemoglobin response in the dose-ranging study.¹
- 141.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hematology – Reblozyl Prior Authorization Policy

- Reblozyl® (luspaterecept-aamt subcutaneous injection – Celgene/Bristol Myers Squibb)

REVIEW DATE: 01/08/2025

OVERVIEW

Reblozyl, an erythroid maturation agent, is indicated for the following conditions:¹

- **Beta-thalassemia**, for the treatment of adults with anemia who require regular red blood cell (RBC) transfusions.
- **Myelodysplastic syndromes (MDS)**, very low to intermediate-risk, for the treatment of anemia in adults who may require regular RBC transfusions with anemia without previous erythropoiesis-stimulating agent (ESA) use (ESA-naïve).
- **MDS with ring sideroblasts**, very low- to intermediate-risk disease, or with **myelodysplastic/myeloproliferative neoplasm (MDS/MPN)** with ring sideroblasts and thrombocytosis for the treatment of anemic adults who have failed an ESA and require two or more RBC units over 8 weeks.

Clinical Efficacy

Beta-Thalassemia

In the BELIEVE trial, all patients required regular RBC transfusions at baseline, defined as at least six units of packed RBCs in the preceding 24 weeks, with no transfusion-free intervals > 35 days in that timeframe.^{1,2} A response to Reblozyl was defined as a 33% reduction in transfusion requirement from pretreatment baseline and a reduction in transfusion requirements of at least two RBC units during Weeks 13 through 24 compared with pretreatment baseline. The percentage of patients who had a reduction in the transfusion burden of at least 33% from baseline during Weeks 13 through 24 plus a reduction of at least two RBC units over this 12-week interval was greater for patients given Reblozyl (21.4%) vs. patients given placebo (4.5%) [P < 0.001].

MDS or MDS/MPN

In the MEDALIST trial, patients were required to have ring sideroblasts according to World Health Organization criteria (i.e., $\geq 15\%$ or $\geq 5\%$ if *SF3B1* mutation was present).^{1,3} Patients with deletion 5q [del(5q)] were excluded from enrollment. All patients were required to have disease refractory or unlikely to respond to ESAs (unless endogenous erythropoietin level was elevated), and the median pretransfusion hemoglobin level was 7.6 g/dL (range 5 to 10 g/dL). Patients had to require RBC transfusions (two or more RBC units over 8 weeks). During the initial 24 weeks of the trial, 58% of patients had transfusion independence for 8 weeks or longer compared with 13% of patients in the placebo group.¹ In the pivotal MEDALIST trial publication, which primarily involved patients with MDS, improvements in hemoglobin from baseline were sustained through at least Week 25. It is notable that the MDS disease course may evolve over time and potentially lead to loss of response of previously effective agents; thus, close follow-up is appropriate to verify that therapeutic response is maintained.

COMMANDS was an open-label trial that compared Reblozyl with epoetin alfa in patients with very low, low, or intermediate risk MDS or with MDS/MPN with ring sideroblasts and thrombocytosis.^{1,4} Patients were required to have had two to six RBC units in 8 weeks and erythropoietin levels < 500 U/L at screening. The primary endpoint was RBC transfusion independence for at least 12 weeks with a concurrent mean

hemoglobin increase of at least 1.5 g/dL during Weeks 1 to 24 which was met by 58.5% of patients in the Reblozyl group vs. 31.2% of patients in the epoetin alfa group.

Dosing Information

For all indications, the starting dose is 1 mg/kg given subcutaneously once every 3 weeks.¹ Assess and review hemoglobin levels and transfusion record prior to each dose. Discontinue if a patient does not experience a decrease in transfusion burden after 9 weeks of treatment (administration of three doses) at the maximum dose level. For beta-thalassemia, the maximum recommended dose is 1.25 mg/kg given once every 3 weeks. For MDS and MDS/MPN, the maximum dose is 1.75 mg/kg given once every 3 weeks.

Guidelines

The Thalassaemia International Federation published guidelines for the management of transfusion-dependent thalassemia (2021).⁵

- **Chelation therapy** was cited as an effective treatment modality in improving survival, decreasing the risk of heart failure, and decreasing morbidities from transfusional-induced iron overload. The optimal chelation regimen should be individualized and will vary among patients and their clinical status.
- **Allogeneic hematopoietic stem cell transplant (HSCT)** should be offered to patients with beta-thalassemia at an early age, before complications due to iron overload have developed if a human leukocyte antigen (HLA) identical sibling is available. In some clinical circumstances, a matched unrelated donor can be adequate.
- **Reblozyl** can be considered for patients ≥ 18 years of age who require regular RBC transfusions.
- **Zynteglo™** (betibeglogene autotemcel intravenous infusion), a gene therapy, may be an option for selected patients when available. Examples include young patients (12 to 17 years of age) with a β^+ genotype who do not have an HLA-compatible sibling donor. Also, Zynteglo can be considered in patients 17 to 55 years of age with a β^+ genotype who do not have severe comorbidities and are at risk or ineligible to undergo allogeneic HSCT but can otherwise undergo an autologous gene therapy procedure with an acceptable risk.

The National Comprehensive Cancer Network guidelines for MDS (version 1.2025 – November 15, 2024) recommend Reblozyl in the following situations:⁶

- **MDS:** Reblozyl is recommended in various clinical scenarios, some of which are described. Treatment with Reblozyl is supported for lower-risk disease associated with symptomatic anemia with no del(5q), with or without other cytogenetic abnormalities with ring sideroblasts $\geq 15\%$ (or ring sideroblasts $\geq 5\%$ with an *SF3B1* mutation) as a single agent (category 1). Treatment with Reblozyl is supported for lower-risk disease associated with symptomatic anemia with no del(5q), with or without other cytogenetic abnormalities with ring sideroblasts $< 15\%$ (or ring sideroblasts $< 5\%$ with an *SF3B1* mutation) and serum erythropoietin levels ≤ 500 mU/L as a single agent or following no response to an ESA (despite adequate iron stores) [category 2A].
- **MDS/MPN:** Treatment with Reblozyl can be considered for MDS/MPN with an *SF3B1* mutation and thrombocytosis as a single agent (category 2A). Reblozyl can also be used for wild-type *SF3B1* if the patient has thrombocytosis and ring sideroblasts $\geq 15\%$ [category 2A].

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Reblozyl. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Reblozyl as well as the monitoring required for adverse events and long-term efficacy, approval

requires Reblozyl to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Reblozyl is recommended in those who meet ONE of the following criteria:

FDA-Approved Indications

18. Transfusion Dependent Beta-Thalassemia. Approve for the duration noted if the patient meets ONE of the following (A or B):

- A) Initial Therapy.** Approve for 4 months if the patient meets ALL of the following (i, ii, iii, and iv):
- i.** Patient is ≥ 18 years of age; AND
 - ii.** According to the prescriber, the patient requires regular red blood cell transfusions as defined by meeting BOTH of the following (a and b):
 - a)** Patient has received at least 6 units of packed red blood cells within the preceding 24 weeks; AND
 - b)** Patient has not had any transfusion-free period > 35 days within the preceding 24 weeks; AND
 - iii.** Patient has not received a gene therapy for transfusion dependent beta-thalassemia in the past; AND
Note: Examples include Zynteglo (betibeglogene autotemcel intravenous infusion) and Casgevy (exagamglogene autotemcel intravenous infusion).
 - iv.** The medication is being prescribed by or in consultation with a hematologist.
- B) Patient is Currently Receiving Reblozyl.** Approve for 1 year if the patient meets ALL of the following (i and ii):
- i.** According to the prescriber, the patient has experienced a clinically meaningful decrease in transfusion burden as defined by a decrease of at least 2 units in red blood cell transfusion burden over the past 6 months compared with the pretreatment baseline (prior to the initiation of Reblozyl); AND
 - ii.** Patient has not received a gene therapy for transfusion dependent beta-thalassemia in the past.
Note: Examples include Zynteglo (betibeglogene autotemcel intravenous infusion) and Casgevy (exagamglogene autotemcel intravenous infusion).

19. Myelodysplastic Syndrome. Approve for the duration noted if the patient meets ONE of the following (A or B):

- A) Initial Therapy.** Approve for 6 months if the patient meets ALL of the following (i, ii, iii, iv, v, vi, vii, and viii):
- i.** Patient is ≥ 18 years of age; AND
 - ii.** According to the prescriber, the patient has myelodysplastic syndromes and meets ONE of the following (a or b):
 - a)** Ring sideroblast positivity; OR
Note: This is defined as ring sideroblasts $\geq 15\%$ or ring sideroblasts $\geq 5\%$ with an *SF3B1* mutation.
 - b)** Serum erythropoietin level is ≤ 500 mU/mL; AND
 - iii.** Patient has very low- to intermediate-risk myelodysplastic syndromes, as determined by the prescriber; AND
Note: This is determined using the International Prognostic Scoring System (IPSS).

- iv. Patient does not have a confirmed mutation with deletion 5q [del(5q)]; AND
 - v. Patient currently requires blood transfusions, defined as at least two red blood cell units over the previous 8 weeks; AND
 - vi. Pretreatment hemoglobin level is < 10.0 g/dL; AND
 - vii. Reblozyl will not be used in combination with an erythropoiesis stimulating agent; AND
 - viii. The medication is being prescribed by or in consultation with an oncologist or hematologist.
- B) Patient is Currently Receiving Reblozyl.** Approve for 6 months if, according to the prescriber, the patient has experienced a clinically meaningful decrease in transfusion burden or the hemoglobin level has increased by ≥ 1.5 g/dL compared with the pretreatment baseline.
- 3. Myelodysplastic/Myeloproliferative Neoplasm.** Approve for the duration noted if the patient meets ONE of the following (A or B):
- A) Initial Therapy.** Approve for 6 months if the patient meets ALL of the following (i, ii, iii, iv, v, vi, vii, and viii):
- i. Patient is ≥ 18 years of age; AND
 - ii. According to the prescriber, the patient has myelodysplastic/myeloproliferative neoplasm and meets BOTH of the following (a and b):
 - a) Ring sideroblast positivity; AND
Note: This is defined as ring sideroblasts $\geq 15\%$ or ring sideroblasts $\geq 5\%$ with an *SF3B1* mutation.
 - b) Thrombocytosis defined as platelet count $\geq 450 \times 10^9/L$; AND
 - iii. Patient has very low- to intermediate-risk disease, as determined by the prescriber; AND
Note: This is determined using the International Prognostic Scoring System (IPSS).
 - iv. Patient does not have a confirmed mutation with deletion 5q [del(5q)]; AND
 - v. Patient currently requires blood transfusions, defined as at least two red blood cell units over the previous 8 weeks; AND
 - vi. Pretreatment hemoglobin level is < 10.0 g/dL; AND
 - vii. Reblozyl will not be used in combination with an erythropoiesis stimulating agent; AND
 - viii. The medication is being prescribed by or in consultation with an oncologist or hematologist.
- B) Patient is Currently Receiving Reblozyl.** Approve for 1 year if, according to the prescriber, the patient has experienced a clinically meaningful decrease in transfusion burden or the hemoglobin level has increased by ≥ 1.5 g/dL compared with the pretreatment baseline.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Reblozyl is not recommended in the following situations:

- 142.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hematology – Ryplazim Prior Authorization Policy

- Ryplazim® (plasminogen, human-tvmh intravenous infusion – Prometic/Kedrion)

REVIEW DATE: 01/03/2024

OVERVIEW

Ryplazim, a plasma-derived human plasminogen, is indicated for the treatment of **plasminogen deficiency type 1 (hypoplasminogenemia)**.¹

Disease Overview

Congenital plasminogen deficiency is an ultra-rare, autosomal recessive disease affecting approximately 500 patients in the US (estimated prevalence of 1.6 per million individuals).² Female predominance has been reported. The median age of first clinical manifestations has been reported as approximately 10 months in one case series.³ Type 1 deficiency is considered “true” plasminogen deficiency and results in decreased plasminogen antigen and activity levels. Type 2 deficiency is referred to as dysplasminogenemia; plasminogen antigen levels are normal, but functional activity is reduced. Type 2 deficiency is asymptomatic and not clinically relevant. By contrast, type 1 deficiency may present with multisystem disease characterized by fibrin-rich (“woody”) pseudomembranes on mucous membranes.² Treatment of congenital plasminogen deficiency should be coordinated by a hematologist who is knowledgeable about the disorder.⁴

Clinical Efficacy

Clinical efficacy of Ryplazim was evaluated in one Phase II/III pivotal study in patients with plasminogen deficiency type 1 (n = 15).^{1,5} All patients had a baseline plasminogen activity level between < 5% and 45% of normal, as well as biallelic mutations in the *PLG* (plasminogen) gene.¹ The primary clinical efficacy endpoint was overall clinical success. Overall clinical success was defined as 50% of patients with visible or other measurable lesions achieving at least a 50% improvement in lesion number/size or functionality impact from baseline. Patients were not required to have active lesions at baseline; however, they were required to have a history of lesions and symptoms consistent with a diagnosis of congenital plasminogen deficiency. Among the 15 patients in the study, a total of 32 external lesions and 12 internal lesions were evaluated. The majority of lesions were resolved by Week 48; no patients experienced new or recurrent lesions.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Ryplazim. All approvals are provided for the duration noted below. In cases where the approval duration is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Ryplazim as well as the monitoring required for adverse events and long-term efficacy, approval requires Ryplazim to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

01/03/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Coverage of Ryplazim is recommended in those who meet the following criteria:

FDA-Approved Indication

20. Plasminogen Deficiency Type 1 (Hypoplasminogenemia). Approve for the duration noted if the patient meets ONE of the following (A or B):

- A) Initial Therapy.** Approve for 3 months if the patient meets the following (i, ii, and iii):
- i.** Patient has a diagnosis of plasminogen deficiency type 1 confirmed by both of the following:
 - a)** Biallelic mutations in the *PLG* gene; AND
 - b)** Baseline plasminogen activity level (prior to initiating Ryplazim) $\leq 45\%$ of normal based on the reference range for the reporting laboratory; AND
 - ii.** Patient has a history of lesions and symptoms consistent with a diagnosis of congenital plasminogen deficiency; AND
 - iii.** Ryplazim is prescribed by or in consultation with a hematologist.
- B) Patient is Currently Receiving Ryplazim.** Approve for 1 year if the patient meets the following (i and ii):
- i.** Patient meets ONE of the following (a or b):
 - a)** Patient has had a clinical response to Ryplazim, as determined by the prescriber; OR
Note: Examples of clinical response include resolution of active lesions, stabilization of current lesions, and prevention of new or recurrent lesions.
 - b)** Patient has a trough plasminogen activity level $\geq 10\%$ (absolute change in plasminogen activity) above the baseline trough level (prior to initiating Ryplazim); AND
 - ii.** Ryplazim is prescribed by or in consultation with a hematologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Ryplazim is not recommended in the following situations:

143. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hematology – Rytelo Prior Authorization Policy

- Rytelo® (imetelstat intravenous infusion – Geron)

REVIEW DATE: 06/12/2024

OVERVIEW

Rytelo, an oligonucleotide telomerase inhibitor, is indicated for the treatment of **transfusion-dependent anemia** in adults with **low- to intermediate-1 risk myelodysplastic syndrome (MDS)** requiring ≥ 4 red blood cell units over 8 weeks who have not responded to, have lost response to, or are ineligible for erythropoiesis-stimulating agents (ESAs).¹

Rytelo was not studied in patients with deletion 5q [del(5q)] cytogenetic abnormality.¹ Discontinue if a patient does not experience a decrease in red blood cell transfusion burden after 24 weeks of treatment (administration of 6 doses) or if unacceptable toxicity occurs at any time.

Guidelines

The National Comprehensive Cancer Network guidelines for MDS (version 3.2024 – July 25, 2024) are extensive.² The following NCCN recommendations for Rytelo for the treatment of MDS in lower-risk disease associated with symptomatic anemia are for patients without del(5q) with or without other cytogenic abnormalities. A patient is considered ring sideroblast positive (RS+) if ring sideroblasts are $\geq 15\%$ (or ring sideroblasts $\geq 5\%$ with an SF3B1 mutation). A patient is considered ring sideroblast negative (RS-) if ring sideroblasts $<15\%$ (or ring sideroblasts $<5\%$ with an SF3B1 mutation). The guidelines categorize patients without the del(5q) abnormality on the basis of ring sideroblasts and serum erythropoietin level without specifying red blood cell transfusion burden.

- For patients who are RS- and have a serum erythropoietin ≤ 500 mU/mL, Rytelo is recommended following no response to ESAs (specifically epoetin alfa products or Aranesp) or Reblozyl® (luspatercept-aamt subcutaneous injection) (**category 1**). For patients who are RS- and have a serum erythropoietin > 500 mU/mL, Rytelo is listed as an “Other Recommended Regimen” to the preferred (azacitidine injection) [category 2A] for patients with a poor probability to respond to immunosuppressive therapy and/or following no response or an intolerance to immunosuppressive therapy.
- For patients who are RS+, Rytelo is recommended following no response to Reblozyl if serum erythropoietin ≤ 500 mU/mL (**category 1**) and if serum erythropoietin > 500 mU/mL (category 2A). For patients who are RS+ and have serum erythropoietin > 500 mU/mL, Rytelo is recommended as initial treatment as well as recommended following no response to Reblozyl (both category 2A).

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Rytelo. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Rytelo as well as the monitoring required for adverse events and long-term efficacy, approval requires Rytelo to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Rytelo is recommended in those who meet the following criteria:

FDA-Approved Indication

21. Myelodysplastic Syndrome. Approve for the duration noted if the patient meets ONE of the following (A or B):

A) Initial Therapy. Approve for 6 months if the patient meets ALL of the following (i, ii, iii, iv, v, vi, and vii):

i. Patient is ≥ 18 years of age; AND

ii. According to the prescriber, patient has low- to intermediate-1 risk myelodysplastic syndrome (MDS); AND

Note: MDS risk category is determined using the International Prognostic Scoring System (IPSS).

iii. Patient has transfusion-dependent anemia, defined as requiring transfusion of ≥ 4 red blood cell units over an 8-week period; AND

iv. According to the prescriber, patient has not responded, lost response to, or is ineligible for erythropoiesis-stimulating agents; AND

Note: Examples of erythropoiesis-stimulating agents include an epoetin alfa product (e.g., Epogen, Procrit, or Retacrit), a darbepoetin alfa product (e.g., Aranesp), or a methoxy polyethylene glycol-epoetin beta product (e.g., Mircera).

v. Patient does NOT have deletion 5q [del(5q)] cytogenic abnormality; AND

vi. Rytelo will NOT be used in combination with an erythropoiesis stimulating agent; AND

vii. The medication is being prescribed by or in consultation with an oncologist or hematologist; OR

B) Patient is Currently Receiving Rytelo. Approve for 1 year if, according to the prescriber, the patient has experienced a clinically meaningful decrease in transfusion burden.

Note: For a patient who has not received 6 months (24 weeks) of therapy or who is restarting therapy, refer to Initial Therapy criteria above.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Rytelo is not recommended in the following situations:

144. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hematology – Tretten Prior Authorization Policy

- Tretten® (coagulation Factor XIII A-Subunit [recombinant] intravenous infusion – NovoNordisk)

REVIEW DATE: 12/04/2024

OVERVIEW

Tretten, a coagulation Factor XIII A-Subunit, is indicated for routine prophylaxis of bleeding in congenital factor XIII A-subunit deficiency.¹ The agent is not indicated for use in patients with congenital Factor XIII B-subunit deficiency.

Disease Overview

Congenital Factor XIII deficiency is caused by defects in both Factor XIII_A and Factor XIII_B genes.^{2,3} However, most cases are due to genetic alterations on the Factor XIII_A gene. The estimated prevalence of Factor XIII_A deficiency is one case in 1 to 2 million people. Clinical symptoms include delayed wound healing, bleeding of soft and subcutaneous tissue, recurrent spontaneous miscarriage, and central nervous system (CNS) bleeding, which may be life-threatening. If patients have severe Factor XIII deficiency, early manifestations include bleeding from the umbilical cord or CNS. Prospective data showed that a level of 30% Factor XIII clotting activity is an adequate therapeutic target for most patients. Treatment of Factor XIII deficiency involves use of fresh frozen plasma, cryoprecipitate, Corifact® (Factor XIII concentration intravenous infusion), or Tretten.

Guidelines

The National Bleeding Disorders Foundation Medical and Scientific Advisory Council has guidelines for the treatment of hemophilia and other bleeding disorders (revised October 2024).⁴ Tretten is recommended in patients who have factor XIII deficiency who lack the factor XIII-A subunit. It will not work in patients who only lack factor XIII-B subunit.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Tretten. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Tretten as well as the monitoring required for adverse events and long-term efficacy, approval requires Tretten to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Tretten is recommended for patients who meet the following criteria:

12/04/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

FDA-Approved Indication

- 22. Congenital Factor XIII A-Subunit Deficiency.** Approve for 1 year if the agent is prescribed by or in consultation with a hematologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Tretten is not recommended in the following situations:

- 145. Congenital Factor XIII B-Subunit Deficiency.** Tretten will not work in patients who only lack Factor XIII-B subunit.^{1,2}
- 146.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hematology – Vonvendi Prior Authorization Policy

- Vonvendi® (von Willebrand factor [recombinant] intravenous infusion – Baxalta)

REVIEW DATE: 12/04/2024

OVERVIEW

Vonvendi, a recombinant von Willebrand factor (VWF), is indicated for use in adults ≥ 18 years of age diagnosed with von Willebrand disease (VWD) for:¹

- **On-demand treatment and control** of bleeding episodes.
- **Perioperative management** of bleeding.
- **Routine prophylaxis to reduce the frequency of bleeding episodes in patients with severe Type 3 VWD** receiving on-demand therapy.

Disease Overview

VWD is an inherited bleeding disorder caused by a deficiency or impairment of a protein found in blood called VWF.⁴⁻⁶ VWF is a plasma protein with a dual role in hemostasis by mediating platelet adhesion at sites of vascular injury and by binding and stabilizing Factor VIII. The disease is rather common as it affects 1 in 100 people; both genders are impacted equally. Symptoms of VWD include mucocutaneous bleeding and excessive hemorrhage following invasive procedures; occasionally, soft tissue hematomas and joint bleeding may also occur. Women who have VWD may experience heavy menorrhagia or experience excessive bleeding at childbirth. Bleeding episodes may be life-threatening in patients with severe forms of VWD. VWD is classified into six types (1, 2A, 2B, 2M, 2N, and 3) according to distinct genotypic, clinical, and laboratory phenotypic characteristics. Type 1 VWD is the most common type (60% to 80% of patients) and represents a partial quantitative deficiency of VWF. Bleeding symptoms are generally mild to moderate. Type 2 VWD affects 15% to 30% of patients and consists of four disease subtypes (2A, 2B, 2M, and 2N) dependent on the specific gene mutation (e.g., decreased VWF-dependent platelet adhesion, decreased binding affinity for Factor VIII). This type is due to a qualitative VWF defect, and the bleeding is generally moderate, but can vary among patients. Type 3 VWD is uncommon (5% to 10% of patients) but is usually severe because it is due to a virtually complete deficiency of VWF. Many patients with VWD also have reduced Factor VIII levels. Treatment options for VWD include desmopressin either parenterally or by a highly concentrated nasal spray (Stimate), Vonvendi, or plasma-derived Factor VIII product that contain VWF.

Guidelines

The National Bleeding Disorders Foundation Medical and Scientific Advisory Council has guidelines for the treatment of hemophilia and other bleeding disorders (revised October 2024).³ Most patients with Type 1 VWD may be treated with a desmopressin product (DDAVP injection or Stimate nasal spray). Some patients with type 2A VWD may respond to DDAVP; a clinical trial with DDAVP should be performed to determine if DDAVP can be used for these particular patients. The guidelines recommend that both DDAVP injection and Stimate not be used in children aged < 2 years and in patients with VWD in whom desmopressin does not provide adequate VWF levels. Also, they should be used cautiously in pregnant women during labor and delivery. Use of plasma-derived VWF-containing Factor VIII concentrates that have VWF is recommended in certain types of VWD that do not respond to therapy with desmopressin (i.e., Type 2B VWD and Type 3 VWD). Also, plasma-derived Factor VIII concentrates that contain VWF (e.g., Alphanate, Humate-P, and Wilate) are recommended in Types 1, 2A, 2M, and 2N VWD who have become transiently unresponsive to DDAVP, as well as in surgical situations, especially in young children

12/04/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

< 2 years of age. Wilate is FDA-approved for routine prophylaxis in children $\geq$ 6 years of age with VWD. Cryoprecipitate should not be utilized to treat patients with VWD except in life- and limb-threatening emergencies when VWD-containing factor VIII concentrate is not immediately available. Vonvendi is available to treat patients with Type 2B and Type 3 VWD; it can also be used in patients with Types 1, 2A, 2M, and 2N VWD who are not responsive to DDAVP and in children < 2 years of age, regardless of VWD type. Vonvendi is approved for use as routine prophylaxis only in patients with severe Type 3 VWD who were previously treated with VWF (recombinant or plasma-derived) on demand. It is produced in Chinese hamster ovary cells and it does not contain human or animal-derived proteins in its cell culture or in its final formulation (a third generation product). Vonvendi contains ultra-large VWF multimers, in addition to the high, medium, and low molecular weight VWF multimers normally found in plasma. Trace amounts of recombinant Factor VIII is in the product as well.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Vonvendi. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Vonvendi as well as the monitoring required for adverse events and long-term efficacy, approval requires Vonvendi to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Vonvendi is recommended in those who meet the following criteria:

FDA-Approved Indication

- 2. Von Willebrand Disease.** Approve for 1 year if the agent is prescribed by or in consultation with a hematologist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Vonvendi is not recommended in the following situations:

- 147.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hemophilia – Altuviiio Prior Authorization Policy

- Altuviiio™ (antihemophilic factor [recombinant] Fc-VWF-XTEN fusion protein-ehtl intravenous infusion – Bioverativ/Sanofi)

REVIEW DATE: 02/28/2024; selected revision 12/04/2024

OVERVIEW

Altuviiio, a recombinant DNA-derived Factor VIII concentrate, is indicated for use in **hemophilia A** in adults and children for:¹

- **Routine prophylaxis** to reduce the frequency of bleeding episodes.
- **On-demand treatment and control** of bleeding episodes.
- **Perioperative management** of bleeding.

It is notable that Altuviiio has demonstrated a 3- to 4-fold prolonged half-life relative to other standard and extended half-life products.¹

Disease Overview

Hemophilia A is an X-linked bleeding disorder primarily impacting males caused by a deficiency in Factor VIII.²⁻⁵ In the US, the incidence of hemophilia A in males is 1:5,000 with an estimated 20,000 people in the US living with hemophilia A. The condition is characterized by bleeding in joints, either spontaneously or in a provoked joint by trauma. Bleeding can occur in many different body areas as well (e.g., muscles, central nervous system). The bleeding manifestations can lead to substantial morbidity such as hemophilic arthropathy. Disease severity is usually defined by the plasma levels or activity of Factor VIII classified as follows: severe (levels < 1% of normal), moderate (levels 1% to 5% of normal), and mild (levels > 5% to < 40% of normal); phenotypic expression may vary. Approximately 50% of patients with hemophilia A are categorized as having severe disease.

Guidelines

Guidelines have not addressed Altuviiio. Guidelines for hemophilia from the National Bleeding Disorders Foundation (August 2023)⁶ and the World Federation of Hemophilia (2020)⁷ recognize the important role of Factor VIII products and Hemlibra® (emicizumab-kxwh subcutaneous injection) in the management of hemophilia A in patients. The National Bleeding Disorders Foundation recognize Altuviiio as a product with a prolonged half-life.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Altuviiio. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Altuviiio, as well as the monitoring required for adverse events and long-term efficacy, the agent is required to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

02/28/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Altuviiio is recommended in those who meet the following criteria:

FDA-Approved Indication

23. Hemophilia A. Approve for 1 year if the patient meets ONE of the following (A or B):

- A) Initial Therapy.** Approve if the patient meets ALL of the following (i, ii, and iii):
- i.** Altuviiio is being used in at least ONE of the following scenarios (a, b, or c):
 - a)** Routine prophylaxis; OR
 - b)** On-demand treatment and control of bleeding episodes; OR
 - c)** Perioperative management of bleeding; AND
 - ii.** Patient meets ONE of the following (a or b):
 - a)** Patient meets BOTH of the following [(1) and (2)]:
 - (1)** Factor VIII inhibitor testing has been performed within the past 30 days; AND
 - (2)** Patient does not have a positive test for Factor VIII inhibitors ≥ 1.0 Bethesda units/mL;
OR
 - b)** Patient has not received Factor VIII therapy in the past; AND
 - iii.** Medication is prescribed by or in consultation with a hemophilia specialist.
- B) Patient Currently Receiving Altuviiio or Has Received Altuviiio in the Past.** Approve if the patient meets ALL of the following (i, ii, and iii):
- i.** Altuviiio is being used in at least ONE of the following scenarios (a, b, or c):
 - a)** Routine prophylaxis; OR
 - b)** On-demand treatment and control of bleeding episodes; OR
 - c)** Perioperative management of bleeding; AND
 - ii.** Patient meets ONE of the following (a or b):
 - a)** Patient meets BOTH of the following [(1) and (2)]:
 - (1)** Factor VIII inhibitor testing has been performed within the past 365 days; AND
 - (2)** Patient does not have a positive test for Factor VIII inhibitors ≥ 1.0 Bethesda units/mL;
OR
 - b)** According to the prescriber, the patient does not have clinical manifestations suggesting the presence of Factor VIII inhibitors; AND
Note: Inhibitors may be present if bleeding is not well controlled, there is decreased responsiveness to Factor VIII therapy, and/or if expected Factor VIII activity plasma levels are not achieved.
 - iii.** Medication is prescribed by or in consultation with a hemophilia specialist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Altuviiio is not recommended in the following situations:

- 148.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hemophilia – Eptacog Products – NovoSeven RT Prior Authorization Policy

- NovoSeven® RT (coagulation Factor VIIa [recombinant] intravenous infusion – Novo Nordisk)

REVIEW DATE: 12/04/2024

OVERVIEW

NovoSeven RT is indicated for the treatment of bleeding episodes and perioperative management in the following conditions:¹

- **Congenital Factor VII deficiency** in adults and children;
- **Glanzmann's thrombasthenia** with refractoriness to platelet transfusions in adults and children, with or without antibodies to platelets;
- **Hemophilia, acquired** in adults; and
- **Hemophilia A or B with inhibitors** in adults and children.

Of note, off-label use of NovoSeven RT in the general population has been suggested in a variety of acute bleeding scenarios (e.g., trauma, intracranial hemorrhage). A 2012 Cochrane Review concluded that the effectiveness of recombinant activated Factor VIIa as a general hemostatic drug in non-hemophiliac patients remains unproven and that use outside its licensed indications should be limited to clinical trials.² Various reviews and clinical practice guidelines concur that the evidence is insufficient to support use of NovoSeven RT as a hemostatic agent outside of its labeled uses.³⁻⁵

Guidelines

The National Bleeding Disorders Foundation Medical and Scientific Advisory Council (MASAC) guidelines (updated October 2024) support NovoSeven RT as a treatment option for inherited **hemophilia A or B with inhibitors, acquired hemophilia A** (other forms of acquired hemophilia not addressed), and **Factor VII deficiency**.⁶ Glanzmann's thrombasthenia is not addressed in the guideline. MASAC recommendations (2013) also state that recombinant Factor VIIa has demonstrated efficacy and safety for prophylactic use for patients with inhibitors in hemophilia A and hemophilia B.⁷

Regarding **hemophilia A and B with inhibitors**, World Federation of Hemophilia guidelines (2020) support recombinant Factor VIIa for patients with high-titer inhibitors who require acute treatment or around surgery/invasive procedures.⁸ For low-titer inhibitors, Factor VIII or IX replacement may be used. These products may also be used for patients with a history of a high-titer inhibitor whose titer has fallen to low or undetectable levels. However, once an anamnestic response occurs, further treatment with Factor replacement is typically no longer effective, and bypass agent therapy (e.g., recombinant Factor VIIa) is needed. National Bleeding Disorders MASAC guidelines (updated October 2024) have similar recommendations: treatment for patients with inhibitors depends on multiple factors, including type of inhibitor (high- or low-responding), current titer, location of bleed, and previous response.⁶

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of NovoSeven RT. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with NovoSeven RT as well as the monitoring required for adverse events and

12/04/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

long-term efficacy, approval requires NovoSeven RT to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of NovoSeven RT is recommended in those who meet one of the following criteria:

FDA-Approved Indications

- 24. Congenital Factor VII Deficiency.** Approve for 1 year if NovoSeven RT is prescribed by or in consultation with a hemophilia specialist.
- 25. Glanzmann's Thrombasthenia.** Approve for 1 year if the patient meets BOTH of the following (A and B):
- A)** Patient is refractory to platelet transfusions; AND
 - B)** The medication is prescribed by or in consultation with a hematologist.
- 26. Hemophilia, Acquired.** Approve for 1 year if the patient meets BOTH of the following (A and B):
- A)** Patient is ≥ 18 years of age; AND
 - B)** The medication is prescribed by or in consultation with a hemophilia specialist.
- 27. Hemophilia A with Inhibitors.** Approve for 1 year if the patient meets BOTH of the following (A and B):
- A)** Patient meets ONE of the following (i, ii, or iii):
 - i.** Patient has a positive inhibitor titer ≥ 5 Bethesda Units; OR
 - ii.** Patient has a history of an inhibitor with anamnestic response to Factor VIII replacement therapy, which, according to the prescriber, precludes the use of Factor VIII replacement to treat bleeding episodes; OR
 - iii.** Patient has a history of an inhibitor with refractory hemostatic response to increased Factor VIII dosing, which, according to the prescriber, precludes the use of Factor VIII replacement to treat bleeding episodes; AND
 - B)** The medication is prescribed by or in consultation with a hemophilia specialist.
- 28. Hemophilia B with Inhibitors.** Approve for 1 year if the patient meets BOTH of the following (A and B):
- A)** Patient meets ONE of the following (i, ii, or iii):
 - i.** Patient has a positive inhibitor titer ≥ 5 Bethesda Units; OR
 - ii.** Patient has a history of an inhibitor with anamnestic response to Factor IX replacement therapy, which, according to the prescriber, precludes the use of Factor IX replacement to treat bleeding episodes; OR
 - iii.** Patient has a of an inhibitor with refractory hemostatic response to increased Factor IX dosing, which, according to the prescriber, precludes the use of Factor IX replacement to treat bleeding episodes; AND
 - B)** The medication is prescribed by or in consultation with a hemophilia specialist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of NovoSeven RT is not recommended in the following situations:

- 149. Bleeding Associated with Liver Disease.** Randomized trials have failed to show benefit of NovoSeven RT in controlling upper gastrointestinal bleeding and variceal bleeding in patients with advanced liver disease.^{9,10} American Association for the Study of Liver Disease guidelines for portal hypertensive bleeding in cirrhosis (2016) state that recombinant Factor VIIa should not be used to correct coagulopathy in this scenario.¹¹
- 150.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hemophilia – Eptacog Products – Sevenfact Prior Authorization Policy

- Sevenfact® (Factor VIIa [recombinant]-jncw intravenous infusion – LFB S.A./Hema Biologics)

REVIEW DATE: 12/04/2024

OVERVIEW

Sevenfact, a recombinant Factor VIIa product, is indicated for the treatment and control of bleeding episodes occurring with **hemophilia A or B with inhibitors** in adults and adolescents (≥ 12 years of age).¹ As a limitation of use, Sevenfact is not indicated for the treatment of patients with congenital Factor VII deficiency.

Disease Overview

In hemophilia A and B, antibodies to exogenous clotting factor, known as “inhibitors”, may develop. Approximately 30% of patients with severe hemophilia A and up to 5% of patients with severe hemophilia B develop inhibitors to Factor VIII or Factor IX during their lifetime.² A high-responding inhibitor (≥ 5 Bethesda Units [BU]) tends to persist, whereas low-responding inhibitors of < 5 BU may wane without changes to the treatment regimen. Presence of inhibitors is associated with higher disease burden, increased risk of musculoskeletal complications, pain, physical limitations, and treatment challenges.^{2,3}

Guidelines

National Bleeding Disorders Foundation Medical and Scientific Advisory Council (MASAC) guidelines (revised August 2023) recognize both Sevenfact and NovoSeven RT® (coagulation Factor VIIa [recombinant] intravenous infusion) as treatments for **hemophilia A or B with inhibitors**.⁴ No preference is stated for one agent over the other. It is noted that choice of product depends on multiple factors, including type of inhibitor (low- or high-responding), current titer, location of bleed, and previous response. Of note, NovoSeven RT, but not Sevenfact, is recognized as a treatment option in other settings, such as acquired hemophilia A and congenital Factor VII deficiency.

World Federation of Hemophilia (WFH) guidelines (2020) support recombinant Factor VIIa for patients with high-titer inhibitors who require acute treatment or around surgery/invasive procedures.³ For low-titer inhibitors, Factor VIII or IX replacement may be used. These products may also be used for patients with a history of a high-titer inhibitor whose titer has fallen to low or undetectable levels. However, once an anamnestic response occurs, further treatment with Factor replacement is typically no longer effective, and bypass agent therapy (e.g., recombinant Factor VIIa) is needed.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Sevenfact. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Sevenfact as well as the monitoring required for adverse events and long-term efficacy, approval requires Sevenfact to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

12/04/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Coverage of Sevenfact is recommended in those who meet one of the following criteria:

FDA-Approved Indications

29. Hemophilia A with Inhibitors. Approve for 1 year if the patient meets ALL of the following (A, B, and C):

- A) Patient is ≥ 12 years of age; AND
- B) Patient meets ONE of the following (i, ii, or iii):
 - i. Patient has a positive inhibitor titer ≥ 5 Bethesda Units; OR
 - ii. Patient has a history of anamnestic response to Factor VIII replacement therapy, which, according to the prescriber, precludes the use of Factor VIII replacement to treat bleeding episodes; OR
 - iii. Patient has a history of refractory response to increased Factor VIII dosing, which, according to the prescriber, precludes the use of Factor VIII replacement to treat bleeding episodes; AND
- C) The medication is prescribed by or in consultation with a hemophilia specialist.

30. Hemophilia B with Inhibitors. Approve for 1 year if the patient meets ALL of the following (A, B, and C):

- A) Patient is ≥ 12 years of age; AND
- B) Patient meets ONE of the following (i, ii, or iii):
 - i. Patient has a positive inhibitor titer ≥ 5 Bethesda Units; OR
 - ii. Patient has a history of anamnestic response to Factor IX replacement therapy, which, according to the prescriber, precludes the use of Factor IX replacement to treat bleeding episodes; OR
 - iii. Patient has a of refractory response to increased Factor IX dosing, which, according to the prescriber, precludes the use of Factor IX replacement to treat bleeding episodes; AND
- C) The medication is prescribed by or in consultation with a hemophilia specialist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Sevenfact is not recommended in the following situations:

151. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hemophilia – FEIBA Prior Authorization Policy

- Hemophilia – FEIBA® (anti-inhibitor coagulant complex intravenous infusion – Baxalta/Takeda)

REVIEW DATE: 12/04/2024

OVERVIEW

FEIBA, a human plasma fraction with Factor VIII bypassing activity, is indicated for use in **hemophilia A and B patients with inhibitors** for control and prevention of bleeding episodes, perioperative management, and routine prophylaxis to prevent or reduce the frequency of bleeding episodes.¹ It contains both activated and inactivated forms of Factors II, VII, IX, and X and is thus referred to as activated prothrombin complex concentrate (aPCC).^{1,2} FEIBA is produced from pooled human plasma.¹

Guidelines

Regarding **hemophilia A with inhibitors** and **hemophilia B with inhibitors** (without history of anaphylaxis/allergy to Factor IX), World Federation of Hemophilia guidelines (2020) support aPCC for patients with high-titer inhibitors who require acute treatment or around surgery/invasive procedures.³ For low-titer inhibitors, Factor VIII or IX replacement may be used. These products may also be used for patients with a history of a high-titer inhibitor whose titer has fallen to low or undetectable levels. However, once an anamnestic response occurs, further treatment with Factor replacement is typically no longer effective, and bypass agent therapy (e.g., aPCC) is needed. National Bleeding Disorders Foundation Medical and Scientific Advisory Council (MASAC) guidelines (updated October 2024) have similar recommendations: treatment for patients with inhibitors depends on multiple factors, including type of inhibitor (high- or low-responding), current titer, location of bleed, and previous response.²

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of FEIBA. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with FEIBA as well as the monitoring required for adverse events and long-term efficacy, approval requires these agents to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of FEIBA is recommended in those who meet one of the following criteria:

FDA-Approved Indications

31. Hemophilia A with Inhibitors. Approve for 1 year if the patient meets BOTH of the following (A and B):

A) Patient meets ONE of the following (i, ii, or iii):

i. Patient has a positive inhibitor titer ≥ 5 Bethesda Units; OR

12/04/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- ii. Patient has a history of an inhibitor with anamnestic response to Factor VIII replacement therapy, which, according to the prescriber, precludes the use of Factor VIII replacement to treat bleeding episodes; OR
- iii. Patient has a history of an inhibitor with refractory hemostatic response to increased Factor VIII dosing, which, according to the prescriber, precludes the use of Factor VIII replacement to treat bleeding episodes; AND

B) The medication is prescribed by or in consultation with a hemophilia specialist.

32. Hemophilia B with Inhibitors. Approve for 1 year if the patient meets BOTH of the following (A and B):

A) Patient meets ONE of the following (i, ii, or iii):

- i. Patient has a positive inhibitor titer ≥ 5 Bethesda Units; OR
- ii. Patient has a history of an inhibitor with anamnestic response to Factor IX replacement therapy, which, according to the prescriber, precludes the use of Factor IX replacement to treat bleeding episodes; OR
- iii. Patient has a of an inhibitor with refractory hemostatic response to increased Factor IX dosing, which, according to the prescriber, precludes the use of Factor IX replacement to treat bleeding episodes; AND

B) The medication is prescribed by or in consultation with a hemophilia specialist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of FEIBA is not recommended in the following situations:

152. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hemophilia Factor IX Products Prior Authorization Policy

EXTENDED HALF-LIFE RECOMBINANT PRODUCTS

- Alprolix® (Coagulation Factor IX [recombinant] Fc fusion protein intravenous infusion – Bioverativ/Sanofi)
- Idelvion® (Coagulation Factor IX [recombinant] albumin fusion protein intravenous infusion – CSL Behring)
- Rebinyn® (Coagulation Factor IX [recombinant] glycoPEGylated intravenous infusion – NovoNordisk)

Standard Half-Life Recombinant Products

- BeneFIX® (Coagulation Factor IX [recombinant] intravenous infusion – Wyeth/Pfizer)
- Ixinity® (Coagulation Factor IX [recombinant] intravenous infusion – Medexus)
- Rixubis® (Coagulation Factor IX [recombinant] intravenous infusion – Baxalta/Takeda)

Plasma-Derived Products

- AlphaNine® SD (Coagulation Factor IX [plasma-derived] intravenous infusion – Grifols)
- Profilnine® (Factor IX Complex [plasma-derived] intravenous infusion – Grifols)

REVIEW DATE: 02/28/2024

OVERVIEW

Alprolix, Idelvion, and Rebinyn are extended half-life recombinant Factor IX products; BeneFIX, Ixinity, and Rixubis are standard half-life recombinant Factor IX products; and AlphaNine SD and Profilnine are plasma-derived Factor IX products.¹⁻⁸ All agents are indicated in various clinical scenarios for use in the management of patients with hemophilia B.

Profilnine is also used in patients with Factor II and/or X deficiency.⁹ Some data are available, albeit limited.

Disease Overview

Hemophilia B is a recessive X-linked bleeding disorder caused by mutations in the factor IX gene that leads to the deficiency or absence of the coagulation factor IX.¹⁰⁻¹² It occurs in 1 out of 30,000 male births and affects about 5,000 people in the US. Hemophilia B predominantly occurs in males; however, approximately 10% of females are carriers and are at risk of usually mild bleeding. The severity of bleeding depends on the degree of the factor IX defect and the phenotypic expression. Factor levels of < 1%, 1% to 5%, and > 5% to < 40% are categorized as severe, moderate, and mild hemophilia B, respectively. Patients with mild hemophilia B may only experience abnormal bleeding during surgery, during tooth extractions, or when injured. Patients with moderate hemophilia B generally have prolonged bleeding responses to minor trauma. Severe hemophilia B is marked by spontaneous bleeding such as spontaneous hemarthrosis, soft-tissue hematomas, retroperitoneal bleeding, intracerebral hemorrhage, and delayed bleeding post-surgery. Complications from recurrent bleeding and soft-tissue hematomas include severe arthropathy, and joint contractures, which may lead to pain and disability. The main treatment of hemophilia B is replacement of missing blood coagulation factor with Factor IX products. Factor IX replacement therapy may be used on-demand when bleeding occurs or given as routine prophylaxis with scheduled infusions. Both plasma-derived and recombinant Factor IX products are available. In general, prophylactic therapy has been associated with a reduction in bleeds and improved outcomes for selected patients (e.g., patients

02/28/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

with moderate or severe factor IX deficiency). The goal of therapy is to prevent uncontrolled internal hemorrhage and severe joint damage, and to properly manage bleeding episodes. The development of inhibitors occurs at a lower frequency in patients with severe hemophilia B compared with severe hemophilia A but can occur in up to 5% of patients. Higher doses than that typically used for the uses of standard half-life products can be given if the patient develops an inhibitor.

Guidelines

Guidelines for hemophilia from the National Bleeding Disorders Foundation (2023)¹³ and the World Federation of Hemophilia (2020)¹⁴ recognize the important role of Factor IX products in the management of hemophilia B patients.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of the following Factor IX products: Alprolix, Idelvion, Rebinyn, BeneFIX, Ixinity, Rixubis, AlphaNine, and Profilnine. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with recombinant Factor IX products, as well as the monitoring required for adverse events and long-term efficacy, the agent is required to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of the following Factor IX products is recommended for patients who meet criteria: Alprolix, Idelvion, Rebinyn, BeneFIX, Ixinity, Rixubis, AlphaNine, and Profilnine.

- I.** Coverage of Alprolix, Idelvion, Rebinyn, BeneFIX, Ixinity, and Rixubis is recommended for patients who meet the following criteria:

FDA-Approved Indication

- 33. Hemophilia B.** Approve for 1 year if the agent is prescribed by or in consultation with a hemophilia specialist.

- II.** Coverage of AlphaNine SD and Profilnine is recommended for patients who meet the following criteria:

FDA-Approved Indication

- 1. Hemophilia B.** Approve for 1 year if the agent is prescribed by or in consultation with a hemophilia specialist.

- III.** Coverage of Profilnine is also recommended for patients who meet the following criteria:

Other Uses with Supportive Evidence

- 1. Factor II Deficiency.** Approve Profilnine for 1 year if the agent is prescribed by or in consultation with a hemophilia specialist.

2. **Factor X Deficiency.** Approve Profilnine for 1 year if the agent is prescribed by or in consultation with a hemophilia specialist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of the cited Factor IX products is not recommended in the following situations:

153. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

REVIEW DATE: 02/28/2024

OVERVIEW

For the **management of hemophilia A**, many recombinant Factor VIII products are available, including extended half-life products¹⁻⁴ (Adynovate, Eloctate, Esperoct, and Jivi) as well as standard half-life products (Advate, Afstyla, Kogenate FS, Kovaltry, Novoeight, Nuwiq, Recombinate, and Xyntha).⁵⁻¹³ In general, these products are utilized in various clinical scenarios in the management of patients with hemophilia A. Several standard half-life Factor VIII plasma-derived products are available. Hemofil M is a plasma-derived standard half-life product that does not contain substantial amounts of von Willebrand Factor which is indicated for use in the management of hemophilia A.¹⁴ Plasma-derived Factor VIII products that contain von Willebrand Factor include Alphanate, Humate P, Koate, and Wilate.¹⁵⁻¹⁸ Alphanate, Humate P, and Wilate are indicated for use in clinical scenarios for the management of hemophilia A, as well as in patients with von Willebrand disease (VWD).^{15,16,18} Wilate is the only agent FDA-approved for use in routine prophylaxis in children 6 years of age and older and adults with VWD.¹⁸ However, the other agents have been used in this clinical scenario as well.²⁹ Koate is indicated for the control and prevention of bleeding

episodes or in order to perform emergency elective surgery in patients with hemophilia A.¹⁷ This policy does not include Altuviiio™ (antihemophilic factor [recombinant] Fc-VWF-XTEN fusion protein-ehtl intravenous injection).¹⁹

Disease Overview

Hemophilia A is an X-linked bleeding disorder primarily impacting males caused by a deficiency in Factor VIII.²⁰⁻²⁴ In the US, the incidence of hemophilia A in males is 1:5,000 with an estimated 20,000 people in the US living with hemophilia A. The condition is characterized by bleeding in joints, either spontaneously or in a provoked joint. Bleeding can occur in many different body areas as well (e.g., muscles, central nervous system). The bleeding manifestations can lead to substantial morbidity such as hemophilic arthropathy. Disease severity is usually defined by the plasma levels or activity of Factor VIII classified as follows: severe (levels < 1% of normal), moderate (levels 1% to 5% of normal), and mild (levels > 5% to < 40% of normal); phenotypic expression may vary. Approximately 50% of patients with hemophilia A are categorized as having severe disease which may require routine prophylactic Factor VIII therapy.

VWD is a group of inherited bleeding disorders related to defects of von Willebrand Factor (vWF), which is needed to achieve hemostasis.²⁵⁻²⁷ It occurs equally in males and females. The disease leads to bleeding from impaired platelet adhesion and aggregation, which may be accompanied by reduced levels of factor VIII. Mucous membrane and skin bleeding symptoms, as well as bleeding with surgical or other hemostatic challenges, may occur. The prevalence of the disease is approximately 1.3%. Pregnancy can increase vWF levels and confound the diagnosis. The three major subtypes of VWD include: partial quantitative vWF deficiency (type 1, 75% of patients); qualitative vWF deficiency (type 2, 25% of patients); and complete vWF deficiency (type 3, rare). Type 2 disease is further divided into four variants (2A, 2B, 2M, 2N) on the basis of the phenotype. In type 3 VWD, Factor VIII levels are usually very low. Acquired von Willebrand syndrome may result but is rare, occurring in fewer than one in 100,000 adults. The bleeding risk varies between modest increases in bleeding which occur only with procedures to a major risk of spontaneous hemorrhage. Approaches to the management of VWD involve increasing plasma concentrations of vWF through stimulation with desmopressin; replacing vWF by using human plasma-derived viral inactivated concentrates; and promoting hemostasis by use of hemostatic agents with mechanisms other than increasing vWF; and Vonvendi® (von Willebrand factor [recombinant] intravenous infusion). Regular prophylaxis is not frequently required.

Guidelines

Guidelines for hemophilia from the National Hemophilia Foundation (2022)²⁰ and the World Federation of Hemophilia (2020)²⁸ recognize the important role of Factor VIII products in the management of hemophilia A. Also, Factor VIII products that contain vWF have a role in the management of VWD.²³

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of the following Factor VIII products: Adynovate, Eloctate, Esperoct, Jivi, Advate, Afstyla, Kogenate FS, Kovaltry, Novoeight, Nuwiq, Recombinate, Xyntha, Hemofil M, Alphanate, Humate-P, Koate, and Wilate. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with recombinant Factor VIII products, as well as the monitoring required for adverse events and long-term efficacy, the agent is required to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

- I. Coverage of Adynovate, Elocate, Esperoct, Jivi, Advate, Afstyla, Kogenate FS, Kovaltry, Novoeight, Nuwiq, Recombinate, and Xyntha is recommended in those who meet the following criteria:

FDA-Approved Indication

34. **Hemophilia A.** Approve the requested agent for 1 year if the agent is prescribed by or in consultation with a hemophilia specialist.

- II. Coverage of Hemofil M and Koate is recommended in those who meet the following criteria:

FDA-Approved Indication

1. **Hemophilia A.** Approve the requested agent for 1 year if the agent is prescribed by or in consultation with a hemophilia specialist.

- III. Coverage of Alphanate, Humate-P, and Wilate is recommended in those who meet one of the following criteria:

FDA-Approved Indications

1. **Hemophilia A.** Approve the requested agent for 1 year if the agent is prescribed by or in consultation with a hemophilia specialist.
2. **Von Willebrand Disease.** Approve for 1 year if the agent is prescribed by or in consultation with a hemophilia specialist.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of the cited Factor VIII products is not recommended in the following situations:

154. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hemophilia – Gene Therapy – Beqvez Prior Authorization Policy

- Beqvez™ (fidanacogene elaparvovec-dzkt intravenous infusion – Pfizer)

REVIEW DATE: 05/15/2024

OVERVIEW

Beqvez, an adeno-associated virus (AAV) vector-based gene therapy, is indicated for the treatment of **hemophilia B** (congenital Factor IX deficiency) in adults with moderate to severe disease who: 1) currently use Factor IX prophylaxis therapy; or 2) have current or historical life-threatening hemorrhage; or 3) have repeated, serious spontaneous bleeding episodes, AND do not have neutralizing antibodies to adeno-associated virus serotype Rh74var (AAVRh74var) capsid as detected by an FDA-approved test.¹ The recommended dose of Beqvez is 5×10^{11} vector genomes per kg of body weight given as a one-time (per lifetime) single dose as an intravenous infusion. Dose based on adjusted body weight for those with a body mass index $> 30 \text{ kg/m}^2$.

Disease Overview

Hemophilia B is a genetic bleeding disorder caused by missing or insufficient levels of blood Factor IX, a protein required to produce blood clots to halt bleeding.²⁻⁵ The condition is a rare X-linked bleeding disorder that mainly impacts males. Hemophilia B is four times less common than hemophilia A, which is caused by a relative lack of blood Factor VIII. Approximately 30,000 individuals are living with hemophilia in the US and hemophilia B accounts for around 15% to 20% of hemophilia cases, or around 6,000 patients. Symptoms include heavy or prolonged bleeding following an injury or after a medical procedure. Bleeding can also occur internally into joints, muscles, or internal organs. Spontaneous bleeding events may also occur. Complications in patients with hemophilia B include joint disease and hemarthrosis. Hemophilia B may be diagnosed when bleeding occurs in infancy or later in life for those with milder disease. There is a strong correlation between Factor IX levels and phenotypic expression of bleeding. Normal plasma levels of Factor IX range from 50% to 150%. The disease is classified based on reduced levels. Mild, moderate, and severe hemophilia B is characterized by Factor IX levels ranging from 6% up to 49%, 1% up to 5%, and $< 1\%$, respectively. Besides gene therapies for the treatment of hemophilia B, Factor IX products, both recombinant and plasma-derived, are used routinely to prevent bleeding or are given on-demand to treat bleeding episodes associated with hemophilia B.

Clinical Efficacy

The efficacy of Beqvez was evaluated in one ongoing, prospective, open-label, single-arm, single-dose, multinational, Phase III pivotal trial called BENEENE-2 involving adult males with moderately severe to severe hemophilia B (Factor IX activity $\leq 2\%$) [$n = 45$].¹ All patients completed a prospective lead-in period of at least 6 months in which baseline data were collected while patients were receiving Factor IX products for routine prophylaxis. However, after receipt of Beqvez, use of such products for routine prophylaxis was to be suspended. The trial is ongoing with a planned long-term follow-up of 6 years. Patients were required to be negative for pre-existing neutralizing antibodies to AAVRh74var capsid to participate. Factor IX inhibitors (or a history), uncontrolled human immunodeficiency virus (HIV) infection, or significant liver fibrosis were exclusion criteria. Adequate hepatic and renal function were required. The median follow-up was 2.0 years (range 0.4 to 3.2 years) post-Beqvez administration. The model-derived mean annualized bleeding rate was 4.5 bleeds/year during the baseline lead-in period vs. 2.5 bleeds/year during the post-Beqvez efficacy evaluation period. In total, 60% of patients did not experience any bleeds after receipt of Beqvez; only 29% of patients did not have bleeds in the baseline lead-in period.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Beqvez. Approval is recommended for those who meet the Criteria for the listed indication. Because of the specialized skills required for evaluation and diagnosis of patients treated with Beqvez as well as the monitoring required for adverse events and long-term efficacy, approval requires Beqvez to be prescribed by a physician who specializes in the condition being treated. All approvals are provided for one-time (per lifetime) as a single dose. If claims history is available, verification is required for certain criteria as noted by **[verification in claims history required]**. For the dosing criteria, verification of the appropriate weight-based dosing is required by a Medical Director as noted by **[verification required]**. In the criteria for Beqvez, as appropriate, an asterisk (*) is noted next to the specified gender. In this context, the specified gender is defined as follows: males are defined as individuals with the biological traits of a man, regardless of the individual's gender identity or gender expression. All reviews (approvals and denials) will be forwarded to the Medical Director for evaluation.

Documentation: Documentation is required for use of Beqvez as noted in the criteria as **[documentation required]**. Documentation may include, but is not limited to, chart notes, laboratory results, medical test results, claims records, prescription receipts, and/or other information.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Beqvez is recommended in those who meet the following criteria:

FDA-Approved Indication

35. Hemophilia B. Approve a one-time (per lifetime) single dose if the patient meets ALL of the following (A, B, C, D, E, F, G, H, I, J, K, L, M, N, O, P, and Q):

- A) Patient is male*; AND
- B) Patient is ≥ 18 years of age; AND
- C) Patient has not received a gene therapy for hemophilia B in the past **[verification in claims history required]**; AND

Note: If no claim for Beqvez or Hemgenix (etranacogene dezaparvovec-drlb intravenous infusion) is present (or if claims history is not available), the prescribing physician confirms that the patient has not previously received Beqvez or Hemgenix.

- D) Patient has moderately severe or severe hemophilia B as evidenced by a baseline (without Factor IX replacement therapy) Factor IX level $\leq 2\%$ of normal **[documentation required]**; AND
- E) Patient meets ONE of the following (i, ii, or iii):
 - i. According to the prescribing physician, the patient has a history of use of Factor IX therapy for ≥ 150 exposure days; OR
 - ii. Patient meets BOTH of the following (a and b):
 - a) Patient has a history of life-threatening hemorrhage; AND
 - b) On-demand use of Factor IX therapy was required for this life-threatening hemorrhage; OR
 - iii. Patient meets BOTH of the following (a and b):
 - a) Patient has a history of repeated, serious spontaneous bleeding episodes; AND
 - b) On-demand use of Factor IX therapy was required for these serious spontaneous bleeding episodes; AND

05/15/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- F) Patient does not have neutralizing antibodies to adeno-associated virus serotype Rh74var (AAVRh74var) capsid by an approved test **[documentation required]**; AND
- G) Patient meets ALL of the following (i, ii, and iii):
- i. Factor IX inhibitor titer testing has been performed within 30 days **[documentation required]**; AND
 - ii. Patient is negative for Factor IX inhibitors **[documentation required]**; AND
 - iii. Patient does not have a of Factor IX inhibitors **[documentation required]**; AND
- H) Prophylactic therapy with Factor IX will not be given after Beqvez administration once adequate Factor IX levels have been achieved; AND
- Note: Use of episodic Factor IX therapy is acceptable for the treatment of bleeds and for surgery/procedures if needed as determined by the hemophilia specialist physician.
- I) Patient meets BOTH of the following (i and ii):
- i. Patient does not have an active infection with hepatitis B virus or hepatitis C virus **[documentation required]**; AND
 - ii. Patient is not currently receiving antiviral therapy for a prior hepatitis B virus or hepatitis C virus exposure **[documentation required]**; AND
- J) According to the prescribing physician, the patient does not have uncontrolled human immunodeficiency virus infection; AND
- K) Patient has undergone liver function testing within 30 days and meets ALL of the following (i, ii, iii, and iv):
- i. Alanine aminotransferase level is $\leq$ two times the upper limit of normal **[documentation required]**; AND
 - ii. Aspartate aminotransferase level is $\leq$ two times the upper limit of normal **[documentation required]**; AND
 - iii. Total bilirubin level is $\leq$ 1.5 times the upper limit of normal **[documentation required]**; AND
 - iv. Alkaline phosphatase level is $\leq$ two times the upper limit of normal **[documentation required]**; AND
- L) Patient does not have evidence of advanced liver impairment and/or advanced fibrosis; AND
- Note: For example, liver elastography (e.g., $\geq$ 9 kPa) suggestive of or equal to METAVIR Stage 3 disease.
- M) Within 30 days, the platelet count was $\geq 100 \times 10^9/L$ **[documentation required]**; AND
- N) Within 30 days, creatinine was ≤ 2.0 mg/dL **[documentation required]**; AND
- O) The medication is prescribed by a hemophilia specialist physician; AND
- P) Current patient body weight has been obtained within 30 days **[documentation required]**; AND
- Q) If criteria A through P are met, approve one dose (vials in a kit) of Beqvez to provide for a one-time (per lifetime) single dose of 5×10^{11} vector genomes per kg of body weight by intravenous infusion **[verification required]**. Table 1 provides the number of vials per kit and the National Drug Codes (NDCs) for each kit.
- Note: Dose based on adjusted body weight for those with a body mass index > 30 kg/m² using the following calculation: Dose Weight (kg) = $30 \text{ kg/m}^2 \times [\text{Height (m)}]^2$

* Refer to the Policy Statement.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Beqvez is not recommended in the following situations:

155. **Prior Receipt of Gene Therapy.** Prior receipt of gene therapy was a reason for patient exclusion in the pivotal study.
156. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hemophilia – Gene Therapy – Hemgenix Prior Authorization Policy

- Hemgenix® (etranacogene dezaparvovec-drlb intravenous infusion – CSL Behring and uniQure)

REVIEW DATE: 02/28/2024; selected revision 05/15/2024

OVERVIEW

Hemgenix, an adeno-associated virus (AAV) vector-based gene therapy, is indicated for the treatment of adults with **hemophilia B** (congenital Factor IX deficiency) who: 1) currently use Factor IX prophylaxis therapy; or 2) have current or historical life-threatening hemorrhage; or 3) have repeated, serious spontaneous bleeding episodes.^{1,2} The recommended dose of Hemgenix is 2×10^{13} genome copies per kg of body weight given as a one-time (per lifetime) single dose as an intravenous infusion.

Disease Overview

Hemophilia B is a genetic bleeding disorder caused by missing or insufficient levels of blood Factor IX, a protein required to produce blood clots to halt bleeding.³⁻⁶ The condition is a rare X-linked bleeding disorder that mainly impacts males. Hemophilia B is four times less common than hemophilia A, which is caused by a relative lack of blood Factor VIII. Approximately 30,000 individuals are living with hemophilia in the US and hemophilia B accounts for around 15% to 20% of hemophilia cases, or around 6,000 patients. Symptoms include heavy or prolonged bleeding following an injury or after a medical procedure. Bleeding can also occur internally into joints, muscles, or internal organs. Spontaneous bleeding events may also occur. Complications in patients with hemophilia B include joint disease and hemarthrosis. Hemophilia B may be diagnosed when bleeding occurs in infancy or later in life for those with milder disease. There is a strong correlation between Factor IX levels and phenotypic expression of bleeding. Normal plasma levels of Factor IX range from 50% to 150%. The disease is classified based on reduced levels. Mild, moderate, and severe hemophilia B is characterized by Factor IX levels ranging from 6% up to 49%, 1% up to 5%, and < 1%, respectively. Besides gene therapies for the treatment of hemophilia B, Factor IX products, both recombinant and plasma-derived, are used routinely to prevent bleeding or are given on-demand to treat bleeding episodes associated with hemophilia B.

Clinical Efficacy

The efficacy of Hemgenix was evaluated in a prospective, open-label, single-dose, single-arm, multinational pivotal study called HOPE-B that involved 54 adult males with moderately severe or severe hemophilia B (Factor IX levels $\leq 2\%$).¹ Patients prospectively completed a lead-in period of at least 6 months in which standard care routine Factor IX prophylaxis therapy was given. This was followed by a single intravenous dose of Hemgenix. Patients were permitted to continue Factor IX prophylaxis during Months 0 to 6 after dosing, if needed, until Factor IX levels were adequate. Prior to screening, patients had been on stable prophylactic therapy for at least 2 months and had greater than 150 exposure days of treatment with a Factor IX product.² Factor IX inhibitors (or a history), uncontrolled human immunodeficiency virus (HIV) infection, or advanced liver fibrosis prevented participation. Adequate hepatic and renal function were required. The estimated mean annualized bleeding rate during Months 7 to 18 following Hemgenix treatment was 1.9 bleeds/year compared with 4.1 bleeds/year during the lead-in period (before Hemgenix administration).¹ At 18 months after treatment, Factor IX activity had increased by 34.3%. The HOPE-B trial is ongoing.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Hemgenix is recommended in those who meet the following criteria:

FDA-Approved Indication

36. Hemophilia B. Approve a one-time (per lifetime) single dose if the patient meets ALL of the following (A, B, C, D, E, F, G, H, I, J, K, L, M, N, O, and P):

A) Patient is male*; AND

B) Patient is ≥ 18 years of age; AND

C) Patient has not received a gene therapy for hemophilia B in the past **[verification in claims history required]**; AND

Note: If no claim for Hemgenix or Beqvez (fidanacogene elaparvovec intravenous infusion) is present (or if claims history is not available), the prescribing physician confirms that the patient has not previously received Hemgenix or Beqvez.

D) Patient has moderately severe or severe hemophilia B as evidenced by a baseline (without Factor IX replacement therapy) Factor IX level $\leq 2\%$ of normal **[documentation required]**; AND

E) Patient meets ONE of the following (i, ii, or iii):

i. According to the prescribing physician, the patient has a history of use of Factor IX therapy for ≥ 150 exposure days; OR

ii. Patient meets BOTH of the following (a and b):

a) Patient has a history of life-threatening hemorrhage; AND

b) On-demand use of Factor IX therapy was required for this life-threatening hemorrhage; OR

iii. Patient meets BOTH of the following (a and b):

a) Patient has a history of repeated, serious spontaneous bleeding episodes; AND

b) On-demand use of Factor IX therapy was required for these serious spontaneous bleeding episodes; AND

F) Patient meets ALL of the following (i, ii, and iii):

i. Factor IX inhibitor titer testing has been performed within 30 days **[documentation required]**; AND

- ii. Patient is negative for Factor IX inhibitors **[documentation required]**; AND
- iii. Patient does not have a of Factor IX inhibitors **[documentation required]**; AND
- G) Prophylactic therapy with Factor IX will not be given after Hemgenix administration once adequate Factor IX levels have been achieved; AND
Note: Use of episodic Factor IX therapy is acceptable for the treatment of bleeds and for surgery/procedures if needed as determined by the hemophilia specialist physician.
- H) Patient meets BOTH of the following (i and ii):
 - i. Patient does not have an active infection with hepatitis B virus or hepatitis C virus **[documentation required]**; AND
 - ii. Patient is not currently receiving antiviral therapy for a prior hepatitis B virus or hepatitis C virus exposure **[documentation required]**; AND
- I) According to the prescribing physician, the patient does not have uncontrolled human immunodeficiency virus infection; AND
- J) Patient has undergone liver function testing within 30 days and meets ALL of the following (i, ii, iii, and iv):
 - i. Alanine aminotransferase level is $\leq$ two times the upper limit of normal **[documentation required]**; AND
 - ii. Aspartate aminotransferase level is $\leq$ two times the upper limit of normal **[documentation required]**; AND
 - iii. Total bilirubin level is $\leq$ two times the upper limit of normal **[documentation required]**; AND
 - iv. Alkaline phosphatase level is $\leq$ two times the upper limit of normal **[documentation required]**; AND
- K) Patient does not have evidence of advanced liver impairment and/or advanced fibrosis; AND
Note: For example, liver elastography (e.g., ≥ 9 kPa) suggestive of or equal to METAVIR Stage 3 disease.
- L) Within 30 days, the platelet count was $\geq 50 \times 10^9/L$ **[documentation required]**; AND
- M) Within 30 days, patient meets ONE of the following (i or ii):
 - i. Patient has an estimated creatinine clearance ≥ 30 mL/min **[documentation required]**; OR
 - ii. Creatinine level is $\leq$ two times the upper limit of normal **[documentation required]**; AND
- N) The medication is prescribed by a hemophilia specialist physician; AND
- O) Current patient body weight has been obtained within 30 days **[documentation required]**; AND
- P) If criteria A through O are met, approve one dose (kit) of Hemgenix to provide for a one-time (per lifetime) single dose of 2×10^{13} genome copies per kg of body weight by intravenous infusion **[verification required]**. Table 1 provides the kit size and the National Drug Codes (NDCs).

* Refer to the Policy Statement.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Hemgenix is not recommended in the following situations:

157. **Prior Receipt of Gene Therapy.** Prior receipt of gene therapy was a reason for patient exclusion in the pivotal study.
158. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hemophilia – Gene Therapy – Roctavian Prior Authorization Policy

- Roctavian® (valoctocogene roxaparvovec-rvox intravenous infusion – BioMarin)

REVIEW DATE: 09/11/2024

OVERVIEW

Roctavian, an adeno-associated virus vector-based gene therapy, is indicated for the treatment of adults with severe hemophilia A (congenital Factor VIII deficiency with Factor VIII activity < 1 IU/dL) without pre-existing antibodies to adeno-associated virus serotype 5 detected by an FDA-approved test.¹

Disease Overview

Hemophilia A is an X-linked bleeding disorder primarily impacting males caused by a deficiency in Factor VIII.²⁻⁷ In the US, the incidence of hemophilia A in males is 1:5,000 with an estimated 20,000 people in the US living with hemophilia A. The condition is characterized by bleeding in joints, either spontaneously or in a provoked joint. Bleeding can occur in many different body areas as well (e.g., muscles, central nervous system). The bleeding manifestations can lead to substantial morbidity such as hemophilic arthropathy. Disease severity is usually defined by the plasma levels or activity of Factor VIII classified as follows: severe (< 1 IU/dL), moderate (1 IU/dL to 5 IU/dL), and mild (> 5 IU/dL to < 40 IU/dL); phenotypic expression may vary. Approximately 50% of patients with hemophilia A are categorized as having severe disease. These patients usually require routine prophylaxis with Factor VIII replacement therapy products or Hemlibra® (emicizumab subcutaneous injection) to prevent bleeding.

Clinical Efficacy

The efficacy of Roctavian was evaluated in one open-label, single-group, multinational Phase III trial (GENEr8-1) involving 134 adult males (≥ 18 years of age) with severe hemophilia A (Factor VIII activity level ≤ 1 IU/dL).^{1,8,9} Patients involved in the trial did not have Factor VIII inhibitors (or a history of such inhibitors) and were receiving regular prophylaxis with Factor VIII products. Use of prophylactic Factor VIII therapy was not permitted during the trial, but could be used up to 4 weeks post Roctavian administration to allow the agent to have an effect. Other notable exclusion criteria were active infection, chronic or active hepatitis B or C, immunosuppressive disorder (including HIV), Stage 3 or 4 liver fibrosis, cirrhosis, liver function test abnormalities, a history of thrombosis or thrombophilia, serum creatinine ≥ 1.4 mg/dL, and active malignancy. Patients had to be treated or exposed to Factor VIII concentrates previously for a minimum of 150 exposure days. Use of systemic immunosuppressive agents (not including corticosteroids), or live vaccines within 30 days before Roctavian infusion prevented participation. In the 132 patients who completed more than 51 weeks of follow-up (and were HIV-negative), the mean Factor VIII activity level at Weeks 49 through 52 had increased by 41.9 IU/dL (a non-hemophilic range). Among the 112 patients enrolled from a noninterventional study who had baseline annualized bleeding rate information prospectively collected for at least 6 months before receiving Roctavian (the rollover population), the mean annualized rates of Factor VIII concentrate use and treated bleeding after Week 4 had decreased after Roctavian administration by 98.6% and 83.8%, respectively (P < 0.001 for both comparisons).^{1,8,9} At Year 3 post Roctavian dosing the mean annualized bleeding rate in the rollover population in the efficacy evaluation period was 2.6 bleeds/year compared to a mean baseline of 5.4 bleeds/year (while using Factor VIII therapies); mean Factor VIII activity levels were 21 IU/dL at this timepoint (mild hemophilic range).¹⁰

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Roctavian. Because of the specialized skills required for evaluation and diagnosis of patients treated with Roctavian as well as the monitoring required for adverse events and long-term efficacy, approval requires Roctavian to be prescribed by a physician who specializes in the condition being treated. All approvals are provided for one-time (per lifetime) as a single dose. If claims history is available, verification is required for certain criteria as noted by **[verification in claims history required]**. For the dosing criteria, verification of the appropriate weight-based dosing is required by a Medical Director as noted by **[verification required]**. In the criteria for Roctavian, as appropriate, an asterisk (*) is noted next to the specified gender. In this context, the specified gender is defined as follows: males are defined as individuals with the biological traits of a man, regardless of the individual's gender identity or gender expression. All reviews (approvals and denials) will be forwarded to the Medical Director for evaluation.

Documentation: Documentation is required for use of Roctavian as noted in the criteria as **[documentation required]**. Documentation may include, but is not limited to, chart notes, laboratory results, medical test results, claims records, prescription receipts, and/or other information.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Roctavian is recommended in those who meet the following criteria:

FDA-Approved Indication

- 37. Hemophilia A.** Approve a one-time (per lifetime) single dose if the patient meets ALL of the following (A, B, C, D, E, F, G, H, I, J, K, L, M, N, O, P, Q, R, and S):
- A)** Patient is male*; AND
 - B)** Patient is ≥ 18 years of age; AND
 - C)** Patient has not received Roctavian in the past **[verification in claims history required]**; AND
Note: If no claim for Roctavian is present (or if claims history is not available), the prescribing physician confirms that the patient has not previously received Roctavian.
 - D)** Patient has severe hemophilia A as evidence by a baseline (without Factor VIII replacement therapy) Factor VIII level of < 1 IU/dL **[documentation required]**; AND
 - E)** Patient does not have detectable pre-existing antibodies to adeno-associated virus 5 (AAV5) by an FDA-approved test **[documentation required]**; AND
 - F)** According to the prescribing physician, the patient has a history of use of Factor VIII therapy for at least 150 exposure days; AND
 - G)** Patient meets ALL of the following (i, ii, and iii):
 - i.** Factor VIII inhibitor titer testing has been performed within the past 30 days **[documentation required]**; AND
 - ii.** Patient does not currently have an inhibitor to Factor VIII **[documentation required]**; AND
 - iii.** Patient does not have a history of Factor VIII inhibitors **[documentation required]**; AND
 - H)** Prophylactic therapy with Factor VIII will not be given after Roctavian administration once adequate Factor VIII levels have been achieved; AND
Note: Use of episodic Factor VIII therapy is acceptable for the treatment of bleeds and for surgery/procedures if needed as determined by the hemophilia specialist physician.
 - I)** Patient does not have a known hypersensitivity to mannitol; AND
 - J)** Patient does not have chronic or active hepatitis B **[documentation required]**; AND
 - K)** Patient does not have active hepatitis C **[documentation required]**; AND

09/11/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- L) Patient is not human immunodeficiency virus positive **[documentation required]**; AND
- M) Patient does not have evidence of significant hepatic fibrosis or cirrhosis; AND
- N) Patient meets ONE of the following (i or ii):
- i. Patient has undergone liver function testing within the past 30 days and meets ALL of the following (a, b, c, d, e, and f):
 - a) Alanine aminotransferase levels are ≤ 1.25 times the upper limit of normal **[documentation required]**; AND
 - b) Aspartate aminotransferase levels are ≤ 1.25 times the upper limit of normal **[documentation required]**; AND
 - c) Total bilirubin levels are ≤ 1.25 times the upper limit of normal **[documentation required]**; AND
 - d) Alkaline phosphatase levels are ≤ 1.25 times the upper limit of normal **[documentation required]**; AND
 - e) Gamma-glutamyl transferase levels are ≤ 1.25 times the upper limit of normal **[documentation required]**; AND
 - f) The International Normalized Ratio is < 1.4 **[documentation required]**; OR
 - ii. If the patient had one or more of the laboratory values listed in *Criteria a-f* above that was not at the value specified in *Criteria a-f* above, then a hepatologist has evaluated the patient and has determined that use of Roctavian is clinically appropriate **[documentation required]**; AND
- O) Within the past 30 days, the platelet count was $\geq 100 \times 10^9/L$ **[documentation required]**; AND
- P) Within the past 30 days, the creatinine level was < 1.4 mg/dL **[documentation required]**; AND
- Q) Medication is prescribed by a hemophilia specialist physician; AND
- R) Current patient body weight has been obtained within the past 30 days **[documentation required]**; AND
- S) If criteria A through R are met, approve one dose of Roctavian to provide for a one-time (per lifetime) single dose of 6×10^{13} vector genomes per kg by intravenous infusion **[verification required]**.
- Note: Roctavian is supplied in a carton (NDC 68135-927-48) that contains one single dose vial (NDC 68135-927-01) with an extractable volume of not less than 8 mL, containing 16×10^{13} vector genomes.

* Refer to the Policy Statement.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Roctavian is not recommended in the following situations:

- 159. Prior Receipt of Gene Therapy.** Prior receipt of gene therapy was a reason for patient exclusion in the pivotal trial.
- 160.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hemophilia – Hemlibra Prior Authorization Policy

- Hemlibra® (emicizumab-kxwh subcutaneous injection – Genentech/Roche/Chugai)

REVIEW DATE: 06/05/2024

OVERVIEW

Hemlibra, a bispecific Factor IXa- and Factor X-directed antibody, is indicated for **hemophilia A** (congenital factor VIII deficiency) with or without factor VIII inhibitors for routine prophylaxis to prevent or reduce the frequency of bleeding episodes in adult and pediatric patients ages newborn and older.¹

Hemlibra is recommended to be given as a loading dose by subcutaneous injection once weekly for the first 4 weeks, followed by a maintenance dose given either once weekly, once every 2 weeks, or once every 4 weeks.¹ Discontinue prophylactic use of bypassing medications the day before starting Hemlibra. The prophylactic use of Factor VIII products may be continued during the first week of Hemlibra prophylaxis. If appropriate, a patient or caregiver may self-inject Hemlibra. Self-administration is not recommended for children < 7 years of age.

Disease Overview

Hemophilia A is an X-linked bleeding disorder primarily impacting males caused by a deficiency in Factor VIII.²⁻⁵ In the US, the incidence of hemophilia A in males is 1:5,000 with an estimated 20,000 people in the US living with hemophilia A. The condition is characterized by bleeding in joints, either spontaneously or in a provoked joint by trauma. Bleeding can occur in many different body areas as well (e.g., muscles, central nervous system). The bleeding manifestations can lead to substantial morbidity such as hemophilic arthropathy. Disease severity is usually defined by the plasma levels or activity of Factor VIII classified as follows: severe (levels < 1% of normal), moderate (levels 1% to 5% of normal), and mild (levels > 5% to < 40% of normal); phenotypic expression may vary. Approximately 50% of patients with hemophilia A are categorized as having severe disease.

Guidelines

Various guidelines discuss Hemlibra.⁶⁻⁸

- **National Bleeding Disorders Foundation:** Two documents from the National Bleeding Disorders Foundation's Medical and Scientific Advisory Council (MASAC) provide recommendations regarding Hemlibra.^{6,7} In general, Hemlibra has been shown to prevent or reduce the occurrence of bleeding in patients with hemophilia A in adults, adolescents, children and infants, both with and without inhibitors.⁶ Factor VIII prophylaxis continuation during the week after initiation of Hemlibra is a reasonable approach.⁷ However, because Hemlibra steady-state levels are not achieved until after four weekly doses, it may be reasonable to continue Factor VIII prophylaxis in selected patients based on bleeding history, as well as physical history, until they are ready to initiate maintenance dosing. Factor VIII products may be used for breakthrough bleeding events. Data are limited regarding the use of Hemlibra prophylaxis during immune tolerance induction.
- **World Federation of Hemophilia (WFH):** Guidelines from the WFH regarding hemophilia (2020) feature Hemlibra in a variety of clinical scenarios.⁸ It is noted that the subcutaneous administration permits patients to initiate prophylaxis at a very young age. Other key benefits include its long half-life, high efficacy in bleed prevention, and reduction in bleeding episodes in patients with or without inhibitors.

Safety

06/05/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Hemlibra has a Boxed Warning regarding thrombotic microangiopathy and thromboembolism.¹ Cases of thrombotic microangiopathy and thrombotic events were reported when on average a cumulative amount of > 100 U/kg/24 hours of activated prothrombin complex concentrate (aPCC) was given for 24 hours or more to patients receiving Hemlibra prophylaxis. Monitor for the development of thrombotic microangiopathy and thrombotic events when aPCC is given. Discontinue prophylactic use of bypassing agents the day before starting Hemlibra.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Hemlibra. All approvals are provided for the duration noted below.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Hemlibra is recommended in those who meet one of the following criteria:

FDA-Approved Indications

44. Hemophilia A with Factor VIII Inhibitors. Approve for 1 year if the patient meets ONE of the following (A or B):

N) Initial Therapy. Approve if the patient meets ALL of the following (i, ii, iii, iv, v, and vi):

- i.** Patient is using Hemlibra for routine prophylaxis to prevent or reduce the frequency of bleeding episodes; AND
- ii.** Patient meets ONE of the following (a or b):
 - a)** Patient has had a positive Factor VIII inhibitor titer greater than 5 Bethesda Units; OR
 - b)** Patient has had a positive Factor VIII inhibitor titer less than or equal to 5 Bethesda Units and meets ONE of the following [(1) or (2)]:
 - (1)** Patient has had an anamnestic response (current or past) to Factor VIII product dosing; OR
 - (2)** Patient experienced an inadequate clinical response (current or past) to increased Factor VIII product dosing; AND
- iii.** Prescriber attests that the patient will not be undergoing immune tolerance induction therapy while receiving Hemlibra; AND
- iv.** Prescriber attests the following regarding use of bypassing agents (a and b):
 - a)** If the patient is currently receiving a bypassing agent for prophylaxis, the bypassing agent therapy will be discontinued the day prior to initiation of Hemlibra; AND
 - b)** Prophylactic use of bypassing agents will not occur while using Hemlibra; AND
Note: Use of bypassing agents for the treatment of breakthrough bleeding is permitted. Examples of bypassing agents include NovoSeven RT (coagulation Factor VIIa [recombinant] intravenous infusion), Sevenfact (Factor VIIa [recombinant]-jncw intravenous infusion), and FEIBA (anti-inhibitor coagulant complex intravenous infusion).
- v.** Prescriber attests BOTH of the following regarding Factor VIII products (a and b):
 - a)** If the patient is currently receiving a Factor VIII product for prophylactic use, the Factor VIII product will be discontinued within the initial 4-week loading dose period with Hemlibra; AND
 - b)** Prophylactic use of Factor VIII products will not occur while using Hemlibra; AND
Note: Use of Factor VIII products for the treatment of breakthrough bleeding is permitted.
- vi.** Medication is prescribed by or in consultation with a hemophilia specialist; OR

06/05/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- O) Patient is Currently Receiving Hemlibra.** Approve if the patient meets ALL of the following (i, ii, iii, iv, v, and vi)
- i.** Patient is using Hemlibra for routine prophylaxis to prevent or reduce the frequency of bleeding episodes; AND
 - ii.** Prescriber attests that the patient will not be undergoing immune tolerance induction therapy while receiving Hemlibra; AND
 - iii.** Prescriber attests that prophylactic use of bypassing agents will not occur while using Hemlibra; AND
Note: Use of bypassing agents for the treatment of breakthrough bleeding is permitted. Examples of bypassing agents include NovoSeven RT (coagulation Factor VIIa [recombinant] intravenous infusion), Sevenfact (Factor VIIa [recombinant]-jncw intravenous infusion), and FEIBA (anti-inhibitor coagulant complex intravenous infusion).
 - iv.** Prescriber attests that prophylactic use of Factor VIII products will not occur while using Hemlibra; AND
Note: Use of Factor VIII products for the treatment of breakthrough bleeding is permitted.
 - v.** Medication is prescribed by or in consultation with a hemophilia specialist; AND
 - vi.** Patient experienced a beneficial response to therapy according to the prescriber.
Note: Examples of a beneficial response to therapy include a reduction in bleeding events, in the severity of bleeding episodes, in the number of bleeding events that required treatment, and/or in the number of spontaneous bleeding events.

45. Hemophilia A without Factor VIII Inhibitors. Approve for 1 year if the patient meets ONE of the following (A or B):

A) Initial Therapy. Approve if the patient meets ALL of the following (i, ii, iii, iv, and v):

- i.** Patient is using Hemlibra for routine prophylaxis to prevent or reduce the frequency of bleeding episodes; AND
- ii.** Patient meets ONE of the following (a or b):
 - a)** Patient has severe to moderate severe disease as defined by pretreatment Factor VIII levels $\leq 2\%$ of normal; OR
 - b)** Patient has moderate to mild disease as defined by pretreatment Factor VIII levels greater than 2% to less than 40% of normal and meets ONE of the following [(1), (2), or (3)]:
 - (1)** Patient has experienced a severe, traumatic, or spontaneous bleeding episode as determined by the prescriber; OR
Note: An example is a bleed involving the central nervous system.
 - (2)** Patient has hemophilia-related joint damage, has experienced a joint bleed, or has a specific joint that is subject to recurrent bleeding (presence of a target joint); OR
 - (3)** Patient is in a perioperative situation and/or has an additional clinical scenario regarding bleeding/bleeding risk in which the prescriber determines the use of Hemlibra is warranted.
Note: Examples include iliopsoas bleeding or severe epistaxis.
- iii.** Prescriber attests that prophylactic use of bypassing agent will not occur while using Hemlibra; AND
Note: Examples of bypassing agents include NovoSeven RT (coagulation Factor VIIa [recombinant] intravenous infusion), Sevenfact (Factor VIIa [recombinant]-jncw intravenous infusion), and FEIBA (anti-inhibitor coagulant complex intravenous infusion).
- iv.** Prescriber attests BOTH of the following regarding Factor VIII products (a and b):
 - a)** If receiving a Factor VIII product for prophylactic use, therapy will be discontinued within the initial 4-week loading dose period with Hemlibra; AND
 - b)** Prophylactic use of Factor VIII products will not occur while using Hemlibra; AND
Note: Use of Factor VIII products for the treatment of breakthrough bleeding is permitted.

- v. Medication is prescribed by or in consultation with a hemophilia specialist; OR
- B) Patient is Currently Receiving Hemlibra. Approve if the patient meets ALL of the following (i, ii, iii, iv, and v):
 - i. Patient is using Hemlibra for routine prophylaxis to prevent or reduce the frequency of bleeding episodes; AND
 - ii. Prescriber attests that prophylactic use of bypassing agent will not occur while using Hemlibra; AND

Note: Examples of bypassing agents include NovoSeven RT (coagulation Factor VIIa [recombinant] intravenous infusion), Sevenfact (Factor VIIa [recombinant]-jncw intravenous infusion), and FEIBA (anti-inhibitor coagulant complex intravenous infusion).
 - iii. Prescriber attests that prophylactic use of Factor VIII product will not occur while using Hemlibra; AND

Note: Use of Factor VIII products for the treatment of breakthrough bleeding is permitted.
 - iv. Medication is prescribed by or in consultation with a hemophilia specialist; AND
 - v. Patient experienced a beneficial response to therapy according to the prescriber.

Note: Examples of a beneficial response include a reduction in bleeding events, in the severity of bleeding episodes, in the number of bleeding events that required treatment, and/or in the number of spontaneous bleeding events.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Hemlibra is not recommended in the following situations:

- 27. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hemophilia – Hympavzi Prior Authorization Policy

- Hympavzi™ (marstacimab-hncq subcutaneous injection – Pfizer)

REVIEW DATE: 11/22/2024; selected revision 12/04/2024

OVERVIEW

Hympavzi, a tissue factor pathway inhibitor antagonist, is indicated for routine prophylaxis to prevent or reduce the frequency of bleeding episodes in patients ≥ 12 years of age with 1) hemophilia A (congenital Factor VIII deficiency) without Factor VIII inhibitors, and 2) hemophilia B (congenital Factor IX deficiency) without Factor IX inhibitors.¹

Hympavzi is recommended to be given as a 300 mg loading dose by subcutaneous injection (two 150 mg subcutaneous injections).¹ One week after the loading dose, initiate maintenance dosing of 150 mg once weekly by subcutaneous injection on the same day each week, at any time of the day. After proper training, Hympavzi may be self-administered.

Disease Overview

Hemophilia A and B are genetic bleeding disorders caused by a dysfunction or a deficiency of coagulation Factor VIII and Factor IX, respectively.²⁻⁷ Because hemophilia is an X-linked condition, males are primarily impacted. Patients who have these types of hemophilias are not able to properly form clots in blood and may bleed for a longer time than normal following injury or surgery. Patients may also experience spontaneous bleeding in muscles, joints, and organs. Bleeds may be life-threatening. A main morbidity is hemophilic arthropathy, which limits mobility. It is estimated that 33,000 males are living with hemophilia in the US; hemophilia A accounts for around 80% of the cases (approximately 26,400 patients) and hemophilia B comprises 20% of cases (around 6,600 patients). Hemophilias are often classified as mild, moderate, or severe based on reduced Factor VIII or IX levels. Approximately 50% and 30% of patients with hemophilia A and hemophilia B, respectively, have severe disease. The formation of antibodies (or inhibitors) to factor products is a challenging complication as it causes Factor VIII and Factor IX therapies to be ineffective, which increases bleeding frequency and severity. Antibodies develop in around 30% and 10% of patients with severe hemophilia A and hemophilia B, respectively.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Hympavzi. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Hympavzi as well as the monitoring required for adverse events and long-term efficacy, approval requires Hympavzi to be prescribed by or in consultation with a hemophilia specialist.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Hympavzi is recommended in those who meet one of the following criteria:

FDA-Approved Indications

11/22/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

3. Hemophilia A without Factor VIII Inhibitors. Approve for 1 year if the patient meets ONE of the following (A or B):

- A) Initial Therapy.** Approve if the patient meets ALL of the following (i, ii, iii, iv, v, and vi):
- vii.** Patient is ≥ 12 years of age; AND
 - viii.** Patient is using Hympavzi for routine prophylaxis to prevent or reduce the frequency of bleeding episodes; AND
 - ix.** Patient has severe hemophilia A as evidenced by a baseline (without Factor VIII replacement therapy) Factor VIII level of $< 1\%$; AND
 - x.** Patient meets ONE of the following (a or b):
 - c)** Patient meets BOTH of the following [(1) and (2)]:
 - (1) Factor VIII inhibitor titer testing has been performed within the past 30 days; AND
 - (2) Patient does not have a positive test for Factor VIII inhibitors of ≥ 1.0 Bethesda units/mL; OR
 - d)** Patient has not received Factor VIII therapy in the past; AND
 - xi.** According to the prescriber, prophylactic use of Factor VIII products will not occur while using Hympavzi; AND

Note: Use of Factor VIII products for the treatment of breakthrough bleeding is permitted.

- xii.** The medication is prescribed by or in consultation with a hemophilia specialist.

B) Patient is Currently Receiving Hympavzi. Approve if the patient meets ALL of the following (i, ii, iii, and iv):

- i.** Patient is using Hympavzi for routine prophylaxis to prevent or reduce the frequency of bleeding episodes; AND
- ii.** According to the prescriber, prophylactic use of Factor VIII products will not occur while using Hympavzi; AND

Note: Use of Factor VIII products for the treatment of breakthrough bleeding is permitted.

- iii.** The medication is prescribed by or in consultation with a hemophilia specialist; AND

- iv.** According to the prescriber, patient experienced a beneficial response to therapy.

Note: Examples of a beneficial response to therapy include a reduction in bleeding events, in the severity of bleeding episodes, in the number of bleeding events that required treatment, and/or in the number of spontaneous bleeds.

46. Hemophilia B without Factor IX Inhibitors. Approve for 1 year if the patient meets ONE of the following (A or B):

C) Initial Therapy. Approve if the patient meets ALL of the following (i, ii, iii, iv, v, and vi):

- vi.** Patient is ≥ 12 years of age; AND
- vii.** Patient is using Hympavzi for routine prophylaxis to prevent or reduce the frequency of bleeding episodes; AND
- viii.** Patient has moderately severe or severe hemophilia B as evidenced by a baseline (without Factor IX replacement therapy) Factor IX level $\leq 2\%$; AND
- ix.** Patient meets ONE of the following (a or b):
 - c)** Patient meets BOTH of the following [(1) and (2)]:
 - (1) Factor IX inhibitor titer testing has been performed within the past 30 days; AND
 - (2) Patient does not have a positive test for Factor IX inhibitors of ≥ 1.0 Bethesda units/mL; OR
 - d)** Patient has not received Factor IX therapy in the past; AND
- x.** According to the prescriber, prophylactic use of Factor IX products will not occur while receiving Hympavzi; AND

Note: Use of Factor IX products for the treatment of breakthrough bleeding is permitted.

- xi.** The medication is prescribed by or in consultation with a hemophilia specialist.

- D) Patient is Currently Receiving Hympavzi.** Approve if the patient meets ALL of the following (i, ii, iii, and iv):
- vi.** Patient is using Hympavzi for routine prophylaxis to prevent or reduce the frequency of bleeding episodes; AND
 - vii.** According to the prescriber, prophylactic use of Factor IX products will not occur while using Hympavzi; AND
Note: Use of Factor IX products for the treatment of breakthrough bleeding is permitted.
 - viii.** The medication is prescribed by or in consultation with a hemophilia specialist; AND
 - ix.** According to the prescriber, patient experienced a beneficial response to therapy.
Note: Examples of a beneficial response include a reduction in bleeding events, in the severity of bleeding episodes, in the number of bleeding events that required treatment, and/or in the number of spontaneous bleeding events.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Hympavzi is not recommended in the following situations:

- 161. Concurrent Use with Hemlibra (emicizumab-kxwh subcutaneous injection) in a Patient with Hemophilia A.** Hemlibra is a bispecific factor IXa- and Factor X-directed antibody indicated for routine prophylaxis to prevent or reduce the frequency of bleeding episodes in adults and pediatric patients ages newborn and older with hemophilia A (congenital factor VIII deficiency) with or without factor VIII inhibitors.⁸ Hympavzi has not been studied concurrently with Hemlibra.¹
- 162.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

- POLICY:** Hepatitis C – Epclusa Prior Authorization Policy
- Epclusa® (sofosbuvir/velpatasvir tablets and oral pellets – Gilead)
 - sofosbuvir/velpatasvir tablets (authorized generic to Epclusa – Gilead)

REVIEW DATE: 04/03/2024

OVERVIEW

The fixed-dose combination of sofosbuvir, a hepatitis C virus (HCV) nucleotide analog NS5B polymerase inhibitor, and velpatasvir, an HCV NS5A inhibitor, is indicated for the treatment of **chronic HCV genotype 1 through 6** infection in patients ≥ 3 years of age.¹ In patients with decompensated cirrhosis (Child-Pugh B or C), sofosbuvir/velpatasvir is administered with weight-based ribavirin. The FDA-approved duration of therapy with sofosbuvir/velpatasvir is 12 weeks for all patients.

Guidelines

The American Association for the Study of Liver Diseases/Infectious Diseases Society of America (AASLD/IDSA) provide recommendations for testing, monitoring, and treating HCV (December 19, 2023).² Instances in which the guidelines provide recommendations for sofosbuvir/velpatasvir outside of the FDA-approved indications are outlined below.

With the availability of pangenotypic HCV treatment regimens, HCV genotyping is no longer required prior to treatment initiation for all individuals. Pretreatment genotyping is still recommended in patients with cirrhosis and/or past unsuccessful HCV treatment, because treatment regimens may differ by genotype. However, for treatment-naïve patients without cirrhosis, although genotyping may impact the preferred treatment approach, it is not required if a pangenotypic regimen is used. The recommendations provide a simplified treatment algorithm for treatment-naïve adults where genotyping is not required.² Treatment-naïve adults without cirrhosis are eligible for simplified treatment if they do not have hepatitis B virus (not hepatitis B serum antigen [HBsAg] positive), are not pregnant, do not have hepatocellular carcinoma, and have not had a liver transplantation. In treatment-naïve adults without cirrhosis, the recommended regimens are Mavyret® (glecaprevir/pibrentasvir tablets) for 8 weeks or sofosbuvir/velpatasvir for 12 weeks. Treatment-naïve adults with compensated cirrhosis are also eligible for simplified treatment; however, recommendations are genotype specific. In patients with compensated cirrhosis, the recommended regimen in patients with genotype 1 through 6 is Mavyret for 8 weeks; sofosbuvir/velpatasvir for 12 weeks is recommended in patients with genotype 1, 2, 4, 5, or 6 (patients with genotype 3 require baseline NS5A resistance-associated substitution testing. Those without Y93H can be treated with sofosbuvir/velpatasvir for 12 weeks).

In patients with decompensated cirrhosis, the guidelines offer a recommendation for patients who are ribavirin-ineligible to treat with sofosbuvir/velpatasvir for 24 weeks.² (Note: sofosbuvir/velpatasvir is FDA-approved in this setting in combination with ribavirin for 12 weeks for adult and pediatric patients). In pediatric patients with any genotype, sofosbuvir/velpatasvir with weight-based ribavirin is recommended in patients with prior exposure to an interferon-based regimen ($\pm$ ribavirin) and/or sofosbuvir but no exposure to NS3/4A or NS5A protease inhibitors, with decompensated cirrhosis.

Although Vosevi® (sofosbuvir/velpatasvir/voxilaprevir tablets) is recommended in most instances for adults with no cirrhosis or compensated cirrhosis who have failed treatment with a sofosbuvir-containing regimen, sofosbuvir/velpatasvir is recommended in adults (genotypes 1 through 6) with decompensated

04/03/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

cirrhosis who have failed therapy with a sofosbuvir-containing regimen. In this setting, sofosbuvir/velpatasvir is recommended for 24 weeks in combination with ribavirin. Data are limited to one Phase II study where sofosbuvir/velpatasvir was studied in patients with genotype 1, 2, and 3 who did not respond to velpatasvir-containing regimens including sofosbuvir/velpatasvir and Vosevi.^{2,6} Retreatment with sofosbuvir/velpatasvir + ribavirin for 24 weeks yielded high overall response rates (sustained virologic response 12 weeks post-treatment [SVR12] 91% [n = 63/69]). Among patients with genotype 1 chronic HCV, 97% of patients (n = 36/37) achieved SVR12. In patients with genotype 2 chronic HCV, SVR12 was attained in 95% of patients (n = 13/14) and in patients with genotype 3 chronic HCV, SVR12 was attained in 78% of patients (n = 14/18). Baseline NS5A resistance associated substitutions did not appear to impact SVR rates. No breakdown of the proportion of patients with decompensated cirrhosis was provided in the study.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of sofosbuvir/velpatasvir. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with sofosbuvir/velpatasvir as well as the monitoring required for adverse events and efficacy, approval requires sofosbuvir/velpatasvir to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of sofosbuvir/velpatasvir is recommended in those who meet one of the following:

FDA-Approved Indications

38. Chronic Hepatitis C Virus (HCV) Genotype 1, 2, 3, 4, 5, or 6, No Cirrhosis or Compensated Cirrhosis (Child-Pugh A). Approve for 12 weeks if the patient meets ALL of the following (A, B, C, and D):

- A) Patient is ≥ 3 years of age; AND
- B) Patient meets ONE of the following (i or ii):
 - i. Patient does not have cirrhosis; OR
 - ii. Patient has compensated cirrhosis (Child-Pugh A); AND
- C) Patient has not been previously treated with sofosbuvir/velpatasvir; AND
- D) The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, infectious diseases physician, or a liver transplant physician.

2. Chronic Hepatitis C Virus (HCV) Genotype 1, 2, 3, 4, 5, or 6, Decompensated Cirrhosis (Child-Pugh B or C), Adult. Approve for the duration below if the patient meets ALL of the following (A, B, C, and D):

- A) Patient is ≥ 18 years of age; AND
- B) Patient has decompensated cirrhosis (Child-Pugh B or C); AND
- C) Patient meets ONE of the following (i or ii):
 - i. Patient is ribavirin-eligible, according to the prescriber: Approve for 12 weeks, if the medication is prescribed in combination with ribavirin; OR
 - ii. Patient is ribavirin-ineligible, according to the prescriber: Approve for 24 weeks; AND

D) The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, infectious diseases physician, or a liver transplant physician.

3. **Chronic Hepatitis C Virus (HCV) Genotype 1, 2, 3, 4, 5, or 6, Decompensated Cirrhosis (Child-Pugh B or C), Pediatric Patient.** Approve for 12 weeks if the patient meets ALL of the following (A, B, C, and D):
- A) Patient is ≥ 3 years of age and < 18 years of age; AND
 - B) Patient has decompensated cirrhosis (Child-Pugh B or C); AND
 - C) The medication will be prescribed in combination with ribavirin; AND
 - D) The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, infectious diseases physician, or a liver transplant physician.

Other Uses with Supportive Evidence

4. **Chronic Hepatitis C Virus (HCV), Genotype Unknown/Undetermined.** Approve for 12 weeks if the patient meets ALL of the following (A, B, C, D, E, F, G, and H):
- A) Patient is ≥ 18 years of age; AND
 - B) Patient does not have cirrhosis; AND
 - C) Patient has not previously been treated for hepatitis C virus; AND
 - D) Patient does not have hepatitis B virus; AND
 - E) Patient is not pregnant; AND
 - F) Patient does not have hepatocellular carcinoma; AND
 - G) Patient has not had a liver transplantation; AND
 - H) The medication will be prescribed by or in consultation with a gastroenterologist, hepatologist, infectious diseases physician, or a liver transplant physician.
5. **Chronic Hepatitis C Virus (HCV), Genotype 1, 2, 3, 4, 5, or 6, Decompensated Cirrhosis (Child-Pugh B or C), Prior Null Responder, Prior Partial Responder, and Prior Relapser to sofosbuvir/velpatasvir or Vosevi.** Approve for 24 weeks if the patient meets ALL of the following (A, B, C, D, and E):
- A) Patient is ≥ 3 years of age; AND
 - B) Patient has decompensated cirrhosis (Child-Pugh B or C); AND
 - C) Patient meets ONE of the following (i or ii):
 - i. Patient has been previously treated with sofosbuvir/velpatasvir; OR
 - ii. Patient has previously been treated with Vosevi; AND
 - D) The medication will be prescribed in combination with ribavirin; AND
 - E) The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, infectious diseases physician, or a liver transplant physician.
6. **Patient Has Been Started on sofosbuvir/velpatasvir.** Approve for an indication or condition addressed as an approval in the Recommended Authorization Criteria section (FDA-Approved Indications or Other Uses with Supportive Evidence). Approve the duration described above to complete a course therapy (e.g., a patient who should receive 12 weeks, and has received 3 weeks, should be approved for 9 weeks to complete their 12-week course).

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of sofosbuvir/velpatasvir is not recommended in the following situations:

04/03/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- 163. Hepatitis C Virus (HCV) [any genotype], Combination with Any Other Direct-Acting Antivirals (DAAs) [Not Including Ribavirin].** Sofosbuvir/velpatasvir provides a complete antiviral regimen. Sofosbuvir/velpatasvir is not recommended to be used with other products containing sofosbuvir.
- 164. Pediatric Patient (< 3 Years of Age).** The safety and efficacy of sofosbuvir/velpatasvir have not been established in pediatric patients < 3 years of age.¹
- 165.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hepatitis C – Harvoni Prior Authorization Policy

- Harvoni® (ledipasvir/sofosbuvir tablets and oral pellets – Gilead)
- ledipasvir/sofosbuvir tablets (authorized generic to Harvoni 90 mg/400 mg tablets–Asegua)

REVIEW DATE: 09/11/2024

OVERVIEW

Ledipasvir/sofosbuvir is a fixed-dose combination of ledipasvir, a hepatitis C virus (HCV) NS5A inhibitor, and sofosbuvir, an HCV nucleotide analog NS5B polymerase inhibitor. It is indicated for the treatment of **chronic HCV** infection in patients ≥ 3 years of age in the following instances:¹

- Genotype 1, 4, 5, or 6 infection with or without compensated cirrhosis; and
- Genotype 1 infection with decompensated cirrhosis, in combination with ribavirin; and
- Genotype 1 or 4 infection who are liver transplant recipients with or without compensated cirrhosis, in combination with ribavirin.

Dosing

In adults, the recommended dose of ledipasvir/sofosbuvir is one tablet taken orally once daily with or without food.¹ The recommended dose of ledipasvir/sofosbuvir tablets or pellets in pediatric patients ≥ 3 years of age is based on weight. The ledipasvir/sofosbuvir pellets can be taken in pediatric patients who cannot swallow the tablet formulation. Table 1 below provides the recommended duration of therapy with ledipasvir/sofosbuvir. The ledipasvir/sofosbuvir authorized generic is only available in the 90 mg/400 mg strength tablet; Harvoni is additionally available as a lower strength tablet (45 mg/200 mg) as well as oral pellets (45 mg/200 mg and 33.75 mg/150 mg).

Table 1. Recommended Treatment Duration for ledipasvir/sofosbuvir in Patients ≥ 3 Years of Age with Chronic HCV Genotype 1, 4, 5, or 6.¹

HCV – Hepatitis C virus; * Harvoni for 8 weeks can be considered in treatment-naïve patients without cirrhosis who have pretreatment HCV RNA < 6 million IU/mL; ** Treatment-experienced patients who have failed treatment with either peginterferon alfa + ribavirin or a hepatitis C virus protease inhibitor + peginterferon + ribavirin; † Harvoni for 12 weeks can be considered in treatment-experienced patients with cirrhosis who are eligible for ribavirin. The daily dose of ribavirin is weight-based (1,000 mg for patients < 75 kg and 1,200 mg for those ≥ 75 kg) administered in two divided doses. ‡ In patients with decompensated cirrhosis, the starting dosage of ribavirin is 600 mg and can be titrated up to 1,000 mg for patients < 75 kg and 1,200 mg for those ≥ 75 kg in two divided doses with food. If the starting dosage of ribavirin is not well tolerated, the dosage should be reduced as clinically indicated based on hemoglobin levels. § The daily dosage of ribavirin is weight-based (1,000 mg for patients < 75 kg and 1,200 mg for those ≥ 75 kg) administered orally in two divided doses with food.

Guidelines

The American Association for the Study of Liver Diseases/Infectious Diseases Society of America have simplified recommendations for the management of chronic HCV in adults (December 19, 2023).² In treatment-naïve adults without cirrhosis, the recommended regimens are Mavyret® (glecaprevir/pibrentasvir tablets and oral pellets) for 8 weeks or Epclusa® (sofosbuvir/velpatasvir tablets [generic] and oral pellets) for 12 weeks. In treatment-naïve adults with compensated cirrhosis, the recommended regimens are Mavyret for 8 weeks (genotypes 1 through 6) or sofosbuvir/velpatasvir for 12 weeks (genotypes 1, 2, 4, 5, or 6; patients with genotype 3 require baseline NS5A resistance-associated substitution testing and those without Y93H can be treated with 12 weeks of Epclusa). Additional genotype-specific and/or special circumstance-specific recommendations are also provided for patients falling outside of these parameters.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Ledipasvir/sofosbuvir continues to be recommended in various situations as outlined below in Table 2.

Table 2. AASLD Recommendations for Harvoni.²

Table 2 (continued). AASLD Recommendations for Harvoni.²

AASLD – American Association for the Study of Liver Diseases; DAA – Direct-acting antiviral; Y – Yes; N – No; HCV – Hepatitis C virus; HIV – Human immunodeficiency virus.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of ledipasvir/sofosbuvir. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with ledipasvir/sofosbuvir as well as the monitoring required for adverse events and long-term efficacy, approval requires ledipasvir/sofosbuvir to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of ledipasvir/sofosbuvir is recommended in those who meet one of the following:

FDA-Approved Indications

39. Chronic Hepatitis C Virus (HCV), Genotype 1. Approve for the duration noted if the patient meets ALL of the following (A, B, and C):

A) Patient is ≥ 3 years of age; AND

B) Patient meets ONE of the following (i, ii or iii):

i. Approve for 8 weeks if the patient meets ALL of the following (a, b, c, d, and e):

a) Patient is treatment-naïve; AND

b) Patient does not have cirrhosis; AND

c) Patient does not have human immunodeficiency virus (HIV); AND

Note: Patients with HIV should be reviewed using the same criteria as patients without HIV, using *Criteria ii or iii below*.

d) Patient is not awaiting liver transplantation; AND

Note: Patients awaiting liver transplantation should be reviewed using *Criteria ii or iii below*.

e) Baseline HCV RNA is < 6 million IU/mL; OR

ii. Approve for 12 weeks if the patient meets ONE the following (a, b, or c):

a) Patient is treatment-naïve AND does not meet criterion *Bi* above; OR

Note: Treatment-naïve includes patients with or without HIV who are treatment-naïve with compensated [Child-Pugh A] cirrhosis regardless of baseline HCV RNA, or treatment-naïve patients with or without HIV without cirrhosis and baseline HCV RNA ≥ 6 million IU/mL. This would also include treatment-naïve patients awaiting transplant with compensated [Child-Pugh A] cirrhosis regardless of baseline HCV RNA or treatment-naïve patients awaiting transplant without cirrhosis and baseline HCV RNA ≥ 6 million IU/mL).

b) Patient has previously been treated for HCV and does not have cirrhosis; OR

Note: For patients with compensated cirrhosis [Child-Pugh A] see criterion *Biii* below, for patients with decompensated cirrhosis [Child-Pugh B or C] see criterion *Biic* below.

c) Patient is treatment-naïve or has previously been treated for HCV and meets ALL of the following [(1), (2), and (3)]:

(1) Patient has decompensated (Child-Pugh B or C) cirrhosis; AND

(2) Patient is ribavirin eligible; AND

Note: For ribavirin ineligible patients with decompensated cirrhosis, see criterion *Biiib* below.

- (3) The medication will be prescribed in combination with ribavirin; OR
- iii. Approve for 24 weeks if the patient meets ONE of the following (a or b):
- (1) Patient has previously been treated for HCV and has compensated (Child-Pugh A) cirrhosis; OR
- (2) Patient is treatment-naïve or has previously been treated for HCV and the patient meets BOTH of the following [(1) and (2)]:
- a. Patient has decompensated cirrhosis (Child-Pugh B or C); AND
- b. Patient is ribavirin ineligible, according to the prescriber; AND
- C) The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, infectious diseases physician, or a liver transplant physician.
2. **Chronic Hepatitis C Virus (HCV), Genotypes 4, 5, OR 6.** Approve for 12 weeks if the patient meets BOTH of the following (A and B):
- A) Patient is ≥ 3 years of age; AND
- B) The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, infectious diseases physician, or a liver transplant physician.
3. **Recurrent Hepatitis C Virus (HCV) Post-Liver Transplantation, Genotypes 1 OR 4.** Approve for 12 weeks if the patient meets ALL of the following (A, B, C and D):
- A) Patient is ≥ 3 years of age; AND
- B) Patient has recurrent HCV after a liver transplantation; AND
- C) The medication will be prescribed in combination with ribavirin; AND
- D) The medication is prescribed by or in consultation with one of the following prescribers who is affiliated with a transplant center: a gastroenterologist, hepatologist, infectious diseases physician, or a liver transplant physician.

Other Uses with Supportive Evidence

4. **Recurrent Hepatitis C Virus (HCV) Post-Liver Transplantation, Genotypes 5 OR 6.** Approve for 12 weeks if the patient meets ALL of the following (A, B, C and D):
- A) Patient is ≥ 18 years of age; AND
- B) Patient has recurrent HCV after a liver transplantation; AND
- C) The medication will be prescribed in combination with ribavirin; AND
- D) The medication is prescribed by or in consultation with one of the following prescribers who is affiliated with a transplant center: a gastroenterologist, hepatologist, infectious diseases physician, or a liver transplant physician.

5. **Hepatitis C Virus (HCV) in Kidney Transplant Recipients, Genotypes 1 or 4.** Approve for 12 weeks if the patient meets ALL of the following (A, B, and C):
- A) Patient is ≥ 18 years of age; AND
 - B) Patient is a kidney transplant recipient with HCV; AND
 - C) The medication is prescribed by or in consultation with one of the following prescribers who is affiliated with a transplant center: a gastroenterologist, hepatologist, infectious diseases physician, nephrologist, liver transplant physician, or a renal transplant physician.
6. **Patient Has Been Started on ledipasvir/sofosbuvir.** Approve ledipasvir/sofosbuvir for an indication or condition addressed as an approval in the Recommended Authorization Criteria section (FDA-Approved Indications or Other Uses with Supportive Evidence). Approve for the duration described above to complete a course of therapy (e.g., a patient who should receive 12 weeks and has received 3 weeks, should be approved for 9 weeks to complete their 12-week course).

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of ledipasvir/sofosbuvir is not recommended in the following situations:

166. **Hepatitis C Virus (HCV) [any genotype], Combination with Any Other Direct-Acting Antivirals (DAAs) Not Including Ribavirin.** Ledipasvir/sofosbuvir provides a complete antiviral regimen. Ledipasvir/sofosbuvir is not recommended to be used with other products containing sofosbuvir.
167. **Pediatric Patient (Age < 3 years).** The safety and efficacy of ledipasvir/sofosbuvir have not been established in pediatric patients < 3 years of age.¹
168. **Retreatment with ledipasvir/sofosbuvir in Patients Who Have Previously Received ledipasvir/sofosbuvir (e.g., retreatment in prior null responders, prior partial responders, prior relapse patients, patients who have not completed a course of therapy due to an adverse reaction or for other reasons).** There are other direct-acting antivirals indicated for patients who have previously been treated with ledipasvir/sofosbuvir.
169. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hepatitis C – Mavyret Prior Authorization Policy

- Mavyret® (glecaprevir/pibrentasvir tablets and oral pellets – AbbVie)

REVIEW DATE: 04/03/2024

OVERVIEW

Mavyret, a direct-acting antiviral, contains glecaprevir, a pangenotypic NS3/4A protease inhibitor and pibrentasvir, a pangenotypic NS5A inhibitor.¹ It is indicated for the treatment of **chronic hepatitis C virus (HCV)** in the following scenarios:

- Patients ≥ 3 years of age with genotype 1, 2, 3, 4, 5, or 6 infection without cirrhosis or with compensated cirrhosis (Child-Pugh A).
- Patients ≥ 3 years of age with genotype 1 infection who have previously been treated with a regimen containing an HCV NS5A inhibitor or an NS3/4A protease inhibitor, but not both.

Dosing

The duration of therapy is based on prior treatment experience, genotype, and the presence or absence of cirrhosis (see Tables 1 and 2). In addition, Mavyret is recommended for 12 weeks in patients ≥ 3 years of age who are liver or kidney transplant recipients. Similar to non-transplant recipients, a 16-week treatment duration is recommended in genotype 1-infected patients who are NS5A inhibitor-experienced without prior treatment with an NS3/4A protease inhibitor or in genotype 3-infected patients who are treatment-experienced with regimens containing interferon, pegylated interferon, ribavirin, and/or Sovaldi® (sofosbuvir tablets/oral pellets).

Table 1. Recommended Duration for Treatment-Naïve Patients.¹

HCV – Hepatitis C virus.

Table 2. Recommended Duration for Treatment-Experienced Patients.¹

HCV – Hepatitis C virus; PRS – Prior treatment experience with regimens containing interferon, pegylated interferon, ribavirin, and/or Sovaldi® (sofosbuvir tablets), but no prior treatment experience with an HCV NS3/4A protease inhibitor (PI) or NS5A inhibitor; PI – Protease inhibitor; ¹ Regimens containing Olysio® (simeprevir capsules) and Sovaldi, or Olysio, Victrelis® (boceprevir capsules), or Incivek® (telaprevir tablets) with interferon or pegylated interferon and ribavirin were studied; ² Regimens containing ledipasvir/sofosbuvir or Daklinza® (daclatasvir tablets) + pegylated interferon + ribavirin [unapproved regimen] were studied.

Guidelines

The American Association for the Study of Liver Diseases/Infectious Diseases Society of America (AASLD/IDSA) provide recommendations for testing, monitoring, and treating HCV (October 24, 2022).² Instances in which the guidelines provide recommendations for Mavyret outside of the FDA-approved indications are outlined below.

With the availability of pangenotypic HCV treatment regimens, HCV genotyping is no longer required prior to treatment initiation for all individuals. Pretreatment genotyping is still recommended in patients with cirrhosis and/or past unsuccessful HCV treatment, because treatment regimens may differ by genotype. However, for treatment-naïve patients without cirrhosis, although genotyping may impact the preferred treatment approach, it is not required if a pangenotypic regimen is used. Treatment-naïve adults without cirrhosis are eligible for simplified treatment if they do not have hepatitis B virus (not hepatitis B serum

04/03/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

antigen [HBsAg] positive), are not pregnant, do not have hepatocellular carcinoma, and have not had a liver transplantation. In treatment-naïve adults without cirrhosis, the recommended regimens are Mavyret for 8 weeks or sofosbuvir/velpatasvir for 12 weeks. Additional genotype-specific and/or special circumstance-specific recommendations are also provided for patients falling outside of these parameters. Treatment-naïve adults with compensated cirrhosis are also eligible for simplified treatment. In patients with compensated cirrhosis, the recommended regimen in patients with genotype 1 through 6 is Mavyret for 8 weeks; sofosbuvir/velpatasvir for 12 weeks is recommended in patients with genotype 1, 2, 4, 5, or 6 (patients with genotype 3 require baseline NS5A resistance-associated substitution testing. Those without Y93H can be treated with sofosbuvir/velpatasvir for 12 weeks). Genotype testing is not required for Mavyret as part of the simplified algorithm in patients with compensated cirrhosis.

Mavyret is recognized as a recommended regimen (12 weeks) for the treatment of patients with recurrent HCV post-liver transplantation (without cirrhosis or with compensated cirrhosis).

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Mavyret. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Mavyret as well as the monitoring required for adverse events and efficacy, approval requires Mavyret to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Mavyret is recommended in those who meet one of the following:

FDA-Approved Indications

40. Chronic Hepatitis C Virus (HCV) Genotype 1, 2, 3, 4, 5, or 6, Treatment-Naïve. Approve for 8 weeks if the patient meets ALL of the following (A, B, and C):

- A) Patient is ≥ 3 years of age; AND
- B) Patient is HCV treatment-naïve (the patient has not previously received treatment for their chronic HCV infection); AND
- C) The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, infectious diseases physician, or a liver transplant physician.

41. Chronic Hepatitis C Virus (HCV), Genotype 1, Treatment-Experienced. Approve for the duration noted if the patient meets ALL of the following (A, B, and C):

- A) Patient is ≥ 3 years of age; AND
- B) Patient meets ONE of the following conditions (i, ii, iii, or iv):
 - i. NS5A-Experienced, NS34-Naïve: Approve for 16 weeks if the patient meets ALL of the following (a, b, and c):
 - a) Patient does not have cirrhosis or has compensated cirrhosis (Child-Pugh A); AND
 - b) Patient had a prior null response, prior partial response, or had relapse after prior treatment with one of the following NS5A-inhibitor containing products: Daklinza (daclatasvir tablets), sofosbuvir/velpatasvir, ledipasvir/sofosbuvir; AND
 - c) Patient has not previously been treated with one of the following NS3/4A inhibitor or NS3/4A inhibitor-containing products: Olysio (simeprevir capsules), Victrelis (boceprevir

- capsules), or Incivek (telaprevir tablets), Technivie (ombitasvir/paritaprevir/ritonavir tablets), Viekira Pak (ombitasvir/paritaprevir/ritonavir tablets; dasabuvir tablets, co-packaged), Viekira XR (dasabuvir/ombitasvir/paritaprevir/ritonavir extended-release tablets), Vosevi (sofosbuvir/velpatasvir/voxilaprevir tablets); or Zepatier (elbasvir/grazoprevir tablets); OR
- ii. NS3/4-Experienced, NS5A-Naïve: Approve for 12 weeks if the patient meets ALL of the following (a, b, and c):
- a) Patient does not have cirrhosis or has compensated cirrhosis (Child-Pugh A); AND
 - b) Patient has not previously been treated with one of the following NS5A-inhibitor-containing products: Daklinza (daclatasvir tablets), sofosbuvir/velpatasvir, ledipasvir/sofosbuvir, Technivie (ombitasvir/paritaprevir/ritonavir tablets), Viekira Pak (ombitasvir/paritaprevir/ritonavir tablets; dasabuvir tablets, co-packaged), Viekira XR (dasabuvir/ombitasvir/paritaprevir/ritonavir extended-release tablets), Vosevi (sofosbuvir/velpatasvir/voxilaprevir tablets), or Zepatier (elbasvir/grazoprevir tablets); AND
 - c) Patient had a prior null response, prior partial response, or had relapse after prior treatment with one of the following NS3/4A inhibitor or NS3/4A inhibitor-containing products: Olysio (simeprevir capsules), Victrelis (boceprevir capsules), or Incivek (telaprevir tablets); OR
- iii. Pegylated Interferon/Interferon, Ribavirin, Sovaldi-Experienced: Approve for 8 weeks if the patient meets BOTH of the following (a and b):
- a) Patient does not have cirrhosis; AND
 - b) Patient had a prior null response, prior partial response, or had relapse after prior treatment with one of the following regimens: interferon ± ribavirin, pegylated interferon ± ribavirin, Sovaldi (sofosbuvir tablets/oral pellets) + ribavirin, Sovaldi + pegylated interferon + ribavirin; OR
- iv. Pegylated Interferon/Interferon, Ribavirin, Sovaldi-Experienced: Approve for 12 weeks if the patient meets BOTH of the following (a and b):
- a) Patient has compensated cirrhosis (Child-Pugh A); AND
 - b) Patient had a prior null response, prior partial response, or had relapse after prior treatment with one of the following regimens: interferon ± ribavirin, pegylated interferon ± ribavirin, Sovaldi (sofosbuvir tablets/oral pellets) + ribavirin, Sovaldi + pegylated interferon + ribavirin; AND
- C) The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, infectious diseases physician, or a liver transplant physician.

42. Chronic Hepatitis C Virus (HCV), Genotype 2, 4, 5, or 6, Treatment-Experienced. Approve for the duration noted if the patient meets ALL of the following (A, B, and C):

A) Patient is ≥ 3 years of age; AND

B) Patient meets ONE of the following (i or ii):

i. Approve for 8 weeks if the patient meets BOTH of the following (a and b):

a) Patient does not have cirrhosis; AND

b) Patient had a prior null response, prior partial response, or had relapse after prior treatment with one of the following regimens: interferon $\pm$ ribavirin, pegylated interferon $\pm$ ribavirin, Sovaldi (sofosbuvir tablets/oral pellets)+ ribavirin, Sovaldi + pegylated interferon + ribavirin; OR

ii. Approve for 12 weeks if the patient meets BOTH of the following (a and b):

a) Patient has compensated cirrhosis (Child-Pugh A); AND

b) Patient had a prior null response, prior partial response, or had relapse after prior treatment with one of the following regimens: interferon $\pm$ ribavirin, pegylated interferon $\pm$ ribavirin, Sovaldi (sofosbuvir tablets/oral pellets) + ribavirin, Sovaldi + pegylated interferon + ribavirin; AND

C) The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, infectious diseases physician, or a liver transplant physician.

43. Chronic Hepatitis C Virus (HCV), Genotype 3, Treatment-Experienced. Approve for 16 weeks if the patient meets ALL of the following (A, B, C, and D):

A) Patient is ≥ 3 years of age; AND

B) Patient does not have cirrhosis or has compensated cirrhosis (Child-Pugh A); AND

C) Patient had a prior null response, prior partial response, or had relapse after prior treatment with one of the following regimens: interferon $\pm$ ribavirin, pegylated interferon $\pm$ ribavirin, Sovaldi (sofosbuvir tablets/oral pellets) + ribavirin, Sovaldi + pegylated interferon + ribavirin; AND

D) The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, infectious diseases physician, or a liver transplant physician.

44. Hepatitis C Virus (HCV) Kidney or Liver Transplant Recipient, Genotype 1, 2, 3, 4, 5, or 6. Approve for the duration noted if the patient meets ALL of the following (A, B, C, and D):

A) Patient is ≥ 3 years of age; AND

B) Patient is a kidney or liver transplant recipient with HCV; AND

C) Patient meets ONE of the following (i, ii, or iii):

i. Patient has genotype 2, 4, 5, or 6 HCV: Approve for 12 weeks; OR

ii. Patient has genotype 1 HCV: Approve for the duration below (a or b):

a) NS5A-Experienced, NS3/4-Naïve: Approve for 16 weeks if the patient meets BOTH of the following [(1) and (2)]:

(1) Patient had a prior null response, prior partial response, or had relapse after prior treatment with one of the following NS5A-inhibitor containing products: Daklinza (daclatasvir tablets), sofosbuvir/velpatasvir, ledipasvir/sofosbuvir; AND

(2) Patient has not previously been treated with one of the following NS3/4A inhibitor or NS3/4A inhibitor-containing products: Olysio (simeprevir capsules), Victrelis (boceprevir capsules), or Incivek (telaprevir tablets), Technivie (ombitasvir/paritaprevir/ritonavir tablets), Viekira Pak (ombitasvir/paritaprevir/ritonavir tablets; dasabuvir tablets, co-packaged), Viekira XR (dasabuvir/ombitasvir/paritaprevir/ritonavir extended-release tablets), Vosevi (sofosbuvir/velpatasvir/voxilaprevir tablets); or Zepatier (elbasvir/grazoprevir tablets).

OR

b) Approve for 12 weeks for all other patients with genotype 1 HCV; OR

- iii. **Patient has genotype 3 HCV:** Approve for the duration below (a or b):
 - a) Approve for 16 weeks if the patient had a prior null response, prior partial response, or had relapse after prior treatment with one of the following regimens: interferon ± ribavirin, pegylated interferon ± ribavirin, Sovaldi (sofosbuvir tablets/oral pellets) + ribavirin, Sovaldi + pegylated interferon + ribavirin; OR
 - b) Approve for 12 weeks for all other patients with genotype 3 HCV; AND
- D) The medication is prescribed by or in consultation with one of the following prescribers who is affiliated with a transplant center: gastroenterologist, hepatologist, infectious diseases physician, nephrologist, renal transplant physician, or liver transplant physician.

Other Uses with Supportive Evidence

- 45. Chronic Hepatitis C Virus (HCV), Genotype Unknown/Undetermined.** Approve for 8 weeks if the patient meets ALL of the following (A, B, C, D, E, F, G, and H):
 - A) Patient is ≥ 18 years of age; AND
 - B) Patient meets ONE of the following (i or ii):
 - i. Patient does not have cirrhosis; OR
 - ii. Patient has compensated cirrhosis; AND
 - C) Patient has not previously been treated for hepatitis C virus; AND
 - D) Patient does not have hepatitis B virus; AND
 - E) Patient is not pregnant; AND
 - F) Patient does not have hepatocellular carcinoma; AND
 - G) Patient has not had a liver transplantation; AND
 - H) The medication will be prescribed by or in consultation with a gastroenterologist, hepatologist, infectious diseases physician, or a liver transplant physician.
- 46. Recurrent Hepatitis C Virus (HCV) Post-Liver Transplantation, Genotype 1, 2, 3, 4, 5, or 6.** Approve for 12 weeks if the patient meets ALL of the following (A, B, and C):
 - A) Patient is ≥ 3 years of age; AND
 - B) Patient has recurrent HCV after a liver transplantation; AND
 - C) The medication is prescribed by or in consultation with one of the following prescribers who is affiliated with a transplant center: a gastroenterologist, hepatologist, infectious diseases physician, or liver transplant physician.
- 47. Patient Has Been Started on Mavyret.** Approve for an indication or condition addressed as an approval in the Recommended Authorization Criteria section (FDA-Approved Indications or Other Uses with Supportive Evidence). Approve the duration described above to complete a course therapy (e.g., a patient who should receive 12 weeks, and has received 3 weeks should be approved for 9 weeks to complete their 12-week course).

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Mavyret is not recommended in the following situations:

- 170. Hepatitis C Virus (HCV) Child-Pugh Class B or C Liver Disease (Moderate or Severe Hepatic Impairment).** Mavyret is contraindicated in patients with moderate or severe hepatic impairment (Child-Pugh Class B or C).
- 171. Hepatitis C Virus (HCV) [any genotype], Combination with Any Other Direct-Acting Antivirals.** Mavyret provides a complete antiviral regimen.

PRIOR AUTHORIZATION POLICY

POLICY: Hepatitis C – Sovaldi Prior Authorization Policy

- Sovaldi® (sofosbuvir tablets and oral pellets – Gilead)

REVIEW DATE: 01/24/2024; selected revision 02/28/2024

OVERVIEW

Sovaldi, a hepatitis C virus (HCV) nucleotide analog non-serine (NS)5B polymerase inhibitor, is indicated for the following uses:¹

- **Chronic HCV genotype 1, 2, 3 or 4 infection**, in adults without cirrhosis or with compensated cirrhosis as a component of a combination antiviral treatment.
- **Chronic HCV genotype 2 or 3 infection**, in pediatric patients ≥ 3 years of age without cirrhosis or with compensated cirrhosis in combination with ribavirin.

The place in therapy for Sovaldi has greatly lessened or is non-existent in most cases due to the availability of other direct-acting antivirals (DAAs) with greater efficacy for many genotypes. Regimens with Sovaldi + peginterferon + ribavirin or Sovaldi + weight-based ribavirin are no longer recommended in treatment guidelines with the exception of pediatric patients due to inferior efficacy compared with other all-oral regimens for all genotypes. Table 1 provides pediatric recommendations.

Table 1. Sovaldi Treatment Regimen in Pediatric Patients (≥ 3 years of age).¹

Guidelines

According to the American Association for the Study of Liver Diseases (AASLD) guidelines, weight-based Sovaldi + ribavirin for treatment-naïve or interferon-experienced ($\pm$ ribavirin) children aged ≥ 3 years with genotype 2 or 3, without cirrhosis or with compensated cirrhosis (Child-Pugh A) is no longer favored because pangenotypic ribavirin-free treatments are now available for children as young as 3 years of age.² The AASLD recommends Epclusa® (sofosbuvir/velpatasvir tablets and oral pellets) and Mavyret® (glecaprevir/pibrentasvir tablets and oral pellets) for the treatment of patients ≥ 3 years of age with genotypes 1 through 6 chronic HCV who are treatment-naïve or interferon-experienced, with or without compensated cirrhosis; Harvoni® (ledipasvir/sofosbuvir tablets and oral pellets) is also an option for children ≥ 3 years of age with genotypes 1, 4, 5, or 6 chronic HCV.²

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Sovaldi. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Sovaldi as well as the monitoring required for adverse events and efficacy, approval requires Sovaldi to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Sovaldi is recommended in those who meet one of the following criteria:

FDA-Approved Indications

01/24/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

47. Chronic Hepatitis C Virus (HCV) Genotype 2. Approve for 12 weeks if the patient meets the following (A, B, C, and D):

A) Patient is ≥ 3 years of age and < 18 years of age; AND

B) Patient does not have decompensated cirrhosis (Child-Pugh B or C); AND

Note: Coverage is provided for patients without cirrhosis or with compensated (Child-Pugh A) cirrhosis.

C) The medication will be prescribed in combination with ribavirin; AND

D) The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, infectious diseases physician, or a liver transplant physician.

48. Chronic Hepatitis C Virus (HCV) Genotype 3. Approve for 24 weeks if the patient meets the following (A, B, C, and D):

A) Patient is ≥ 3 years of age and < 18 years of age; AND

B) Patient does not have decompensated cirrhosis (Child-Pugh B or C); AND

Note: Coverage is provided for patients without cirrhosis or for patients with compensated (Child-Pugh A) cirrhosis.

C) The medication will be prescribed in combination with ribavirin; AND

D) The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, infectious diseases physician, or a liver transplant physician.

Other Uses with Supportive Evidence

3. Patient Has Been Started on Sovaldi. Approve for an indication or condition addressed as an approval in the Recommended Authorization Criteria section (FDA-Approved Indications or Other Uses with Supportive Evidence). Approve the duration described above to complete a course therapy (e.g., a patient who should receive 12 weeks and has received 3 weeks should be approved for 9 weeks to complete their 12-week course).

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Sovaldi is not recommended in the following situations:

- 1. HCV (Any Genotype), Combination Use with Direct-Acting Antivirals (DAAs) Other than Ribavirin.** In adults with any genotype chronic HCV with or without compensated cirrhosis who have failed treatment with Mavyret, retreatment with Mavyret + Sovaldi + ribavirin is a recommended regimen based on data from a Phase IIIb study evaluating the safety and efficacy of Mavyret + Sovaldi + weight-based ribavirin as a 12- or 16-week retreatment regimen for patients who experienced virologic failure to Mavyret within the context of a previous clinical trial. Non-cirrhotic Mavyret non-responders with genotype 1, 2, 4, 5, or 6 who were naïve to protease and NS5A inhibitors received 12 weeks Mavyret + Sovaldi and weight-based ribavirin. Patients with genotype 3, and/or compensated cirrhosis, and/or protease/NS5A experience (prior to their initial Mavyret treatment) received 16 weeks of therapy with the same regimen. In a preliminary analysis, 96% (n = 22/23) of these patients achieved SVR with a single relapse in a cirrhotic patient with genotype 1a. Vosevi is also a recommended regimen in this instance and it is FDA-approved for such use.
- 2. Monotherapy with Sovaldi.** Sovaldi is indicated as a component of a combination antiviral treatment regimen for HCV.¹
- 3. Pediatric Patients (Age < 3 years).** The safety and efficacy of Sovaldi have not been established in pediatric patients < 3 years of age.¹

4. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hepatitis C – Vosevi Prior Authorization Policy

- Vosevi® (sofosbuvir/velpatasvir/voxilaprevir tablets – Gilead)

REVIEW DATE: 08/07/2024

OVERVIEW

Vosevi is a direct-acting-antiviral (DAA) containing sofosbuvir, a nucleotide analog NS5B polymerase inhibitor, velpatasvir, a hepatitis C virus (HCV) NS5A inhibitor, and voxilaprevir, an HCV NS3/4A protease inhibitor.¹ It is indicated for the treatment of adults with **chronic HCV** with or without compensated cirrhosis who have:

- Genotype 1, 2, 3, 4, 5, or 6 infection and have previously been treated with an HCV regimen containing an NS5A inhibitor;
- Genotype 1a or 3 infection and who have previously been treated with an HCV regimen containing sofosbuvir without an NS5A inhibitor.

Additional benefit of Vosevi over Epclusa® (sofosbuvir/velpatasvir tablets/oral granules) was not shown in adults with genotype 1b, 2, 4, 5, or 6 infection previously treated with sofosbuvir without an NS5A inhibitor.¹ The recommended dosage of Vosevi is one tablet, taken orally, once daily (QD) with food for 12 weeks.

Guidelines

The American Association for the Study of Liver Diseases guidelines recommend Vosevi in several circumstances in adults, mainly in patients who are direct-acting antiviral-experienced (outlined below). Some of these recommendations are based on very limited data and are not FDA-approved indications for Vosevi (e.g., retreatment with Vosevi in patients who have failed Vosevi in the past [one case report]).

Vosevi is recommended in the following situations:

- **Genotype 1 through 6 chronic HCV, ± compensated cirrhosis, treatment-experienced**
 - Prior sofosbuvir-based treatment failure: Vosevi for 12 weeks; the addition of ribavirin is recommended in patients with genotype 3 HCV with compensated cirrhosis.
 - Prior Mavyret® (glecaprevir/pibrentasvir tablets and oral pellets) treatment failure: Vosevi for 12 weeks; the addition of ribavirin is recommended in patients with compensated cirrhosis.
 - Prior Zepatier® (elbasvir/grazoprevir tablets) treatment failure: Vosevi for 12 weeks; the addition of ribavirin is recommended in patients with compensated cirrhosis.
 - Prior Vosevi treatment failure: Vosevi + ribavirin for 24 weeks.
- **Kidney transplant, genotype 1 through 6 HCV, ± compensated cirrhosis, treatment-experienced**
 - Prior direct-acting antiviral failure: Vosevi ± ribavirin for 12 weeks; the addition of ribavirin should be considered for patients with compensated cirrhosis and multiple negative baseline characteristics.
- **Recurrent HCV post-liver transplantation, genotype 1 through 6 infection of the allograft, ± compensated cirrhosis, treatment-naïve**
 - Prior direct-acting antiviral failure: Vosevi for 12 weeks is recommended; the addition of ribavirin should be considered for patients with compensated cirrhosis and multiple negative baseline characteristics.

08/07/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Vosevi is an alternative recommendation in the following situation:

- **Genotype 3 HCV, compensated cirrhosis, treatment-naïve with Y93H resistance-associated substitution**
 - Vosevi for 12 weeks.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Vosevi. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Vosevi as well as the monitoring required for adverse events and efficacy, approval requires Vosevi to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Vosevi is recommended in those who meet one of the following criteria:

FDA-Approved Indications

48. Chronic Hepatitis C Virus (HCV) Genotype 1b, 2, 4, 5, or 6. Approve for 12 weeks if the patient meets ALL of the following (A, B, C, and D):

- A)** Patient is ≥ 18 years of age; AND
- B)** Patient meets ONE of the following (i or ii):
 - i.** Patient does not have cirrhosis; OR
 - ii.** Patient has compensated cirrhosis (Child-Pugh A); AND
- C)** Patient had a prior null response, prior partial response, or relapse after prior treatment with an HCV direct-acting antiviral regimen containing an NS5A inhibitor; AND
Note: Examples of direct-acting antivirals that are, or contain, an NS5A inhibitor include: Daklinza (daclatasvir tablets), Epclusa (sofosbuvir/velpatasvir tablets/oral pellets), Harvoni (ledipasvir/sofosbuvir tablets/oral pellets), Mavyret (glecaprevir/pibrentasvir tablets/oral pellets), Viekira Pak (ombitasvir/paritaprevir/ritonavir tablets; dasabuvir tablets, co-packaged), Zepatier (elbasvir/grazoprevir tablets).
- D)** The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, infectious diseases physician, or a liver transplant physician.

49. Chronic Hepatitis C Virus (HCV), Genotype 1a or 3. Approve for 12 weeks if the patient meets ALL of the following (A, B, C, and D):

- A)** Patient is ≥ 18 years of age; AND
- B)** Patient meets ONE of the following (i or ii):
 - i.** Patient does not have cirrhosis; OR
 - ii.** Patient has compensated cirrhosis (Child-Pugh A); AND
- C)** Patient meets ONE of the following (i or ii):
 - i.** Patient had a prior null response, prior partial response, or relapse after prior treatment with an HCV direct-acting antiviral regimen containing an NS5A inhibitor; ORNote: Examples of direct-acting antivirals that are, or contain, an NS5A inhibitor include: Daklinza (daclatasvir tablets), Epclusa (sofosbuvir/velpatasvir tablets/oral pellets), Harvoni (ledipasvir/sofosbuvir tablets/oral pellets), Mavyret (glecaprevir/pibrentasvir tablets/oral

- pellets), Viekira Pak (ombitasvir/paritaprevir/ritonavir tablets; dasabuvir tablets, co-packaged), Zepatier (elbasvir/grazoprevir tablets).
- ii. Patient had a prior null response, prior partial response, or relapse after prior treatment with an HCV direct-acting antiviral regimen containing Sovaldi (sofosbuvir tablets/oral pellets) + a non-NS5A inhibitor; AND
- Note: Examples of regimens that contain Sovaldi (sofosbuvir tablets/oral pellets) + a non-NS5A inhibitor include: Sovaldi + NS3 inhibitors (Olysio [simeprevir capsules], Victrelis [boceprevir capsules], or Incivek [telaprevir tablets]) or Sovaldi + ribavirin ± pegylated interferon.
- D) The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, infectious diseases physician, or a liver transplant physician.

Other Uses with Supportive Evidence

- 50. Chronic Hepatitis C Virus (HCV) Genotype 1b, 2, 4, 5, or 6.** Approve for 12 weeks if the patient meets ALL of the following (A, B, C, and D):
- A) Patient is ≥ 18 years of age; AND
- B) Patient meets ONE of the following (i or ii):
- i. Patient does not have cirrhosis; OR
- ii. Patient has compensated cirrhosis (Child-Pugh A); AND
- C) Patient had a prior null response, prior partial response, or relapse after prior treatment with an HCV direct-acting antiviral regimen containing Sovaldi (sofosbuvir tablets/oral pellets) + a non-NS5A inhibitor; AND
- Note: Examples of regimens that contain Sovaldi (sofosbuvir tablets/oral pellets) + a non-NS5A inhibitor include: Sovaldi + NS3 inhibitors (Olysio [simeprevir capsules], Victrelis [boceprevir capsules], or Incivek [telaprevir tablets]) or Sovaldi + ribavirin ± pegylated interferon.
- D) The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, infectious diseases physician, or a liver transplant physician.
- 51. Patient Has Been Started on Vosevi.** Approve for an indication or condition addressed as an approval in the Recommended Authorization Criteria section (FDA-Approved Indications or Other Uses with Supportive Evidence). Approve the duration described above to complete a course of therapy (e.g., a patient who should receive 12 weeks, and has received 3 weeks should be approved for 9 weeks to complete their 12-week course).

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Vosevi is not recommended in the following situations:

- 1. Hepatitis C Virus (HCV) [any genotype], Combination with Any Other Direct-Acting Antivirals (DAAs).** Vosevi provides a complete antiviral regimen.
- 2. Pediatric Patients (Age < 18 Years).** The safety and efficacy of Vosevi have not been established in pediatric patients < 18 years of age.¹
- 3.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hepatitis C – Zepatier Prior Authorization Policy

- Zepatier® (grazoprevir/elbasvir tablets – Merck)

REVIEW DATE: 02/14/2024; selected revision 02/28/2024

OVERVIEW

Zepatier, an oral fixed-dose combination tablet containing grazoprevir, a second generation protease inhibitor and elbasvir, an NS5A inhibitor, is indicated with or without ribavirin for the treatment of genotypes 1 and 4 **chronic hepatitis C virus (HCV)** in adults and pediatric patients ≥ 12 years of age or weighing at least 30 kg.¹

Safety

Zepatier is contraindicated in patients with Child-Pugh B or C liver disease (decompensated cirrhosis). Zepatier is also contraindicated with inhibitors of organic anion transporting polypeptides 1B1/3 that are known or expected to significantly increase grazoprevir plasma concentrations, strong inducers of cytochrome P450 3A, and efavirenz.

Dosing

The duration of treatment is outlined below (Table 1) and is dependent on the patient population. Prior to initiating Zepatier in patients with genotype 1a infection, testing for the NS5A resistance associated polymorphism is recommended to guide treatment duration. In patients with genotype 1a and this polymorphism present at baseline, 12 weeks of treatment with Zepatier resulted in lower rates of sustained viral response 12 weeks after treatment completion relative to patients with genotype 1a without the presence of this baseline polymorphism.

Table 1. Recommended Zepatier Dosage Regimens for the Treatment of Genotype 1 or 4 Chronic HCV.¹

HCV – Hepatitis C virus; TN – Treatment naïve; PR – Pegylated interferon/ribavirin; * Patients who have failed treatment with PR; † NS5A resistance-associated polymorphisms at amino acid positions 28, 30, 31, or 93;[§] The optimal Zepatier-based treatment regimen and duration of therapy for PR + HCV protease inhibitor-experienced genotype 1a-infected patients with one or more baseline NS5A resistance-associated polymorphisms at positions 28, 30, 31, and 93 has not been established; PI – PI – Protease inhibitor; ^β Patients who have failed treatment with PR + and NS3/4A PI (i.e., Victrelis® [boceprevir capsules], Incivek® [telaprevir tablets], or Olysio® [simeprevir capsules]); TE – Treatment-experienced; NA – Not applicable.

Guidelines

According to the American Association for the Study of Liver Diseases (AASLD) [December 2023], NS5A resistance-associated substitution RAS testing is recommended for genotype 1a-infected, treatment-naïve or -experienced patients being considered for Zepatier.² If present, a different regimen should be considered. Zepatier is recognized as an alternative regimen in treatment-naïve patients with Genotype 1a with or without compensated cirrhosis, and a recommended treatment option in patients with genotype 1b or 4 chronic HCV with or without compensated cirrhosis in guidelines. It is also recognized as an alternative regimen in treatment-naïve and non-direct-acting antiviral-experienced kidney transplant patients with genotype 1 or 4 with or without compensated cirrhosis. The pediatric portion of the guidelines have not been updated since the approval of the lower age indication approved with Zepatier.

POLICY STATEMENT

02/14/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Prior Authorization is recommended for prescription benefit coverage of Zepatier. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Zepatier as well as the monitoring required for adverse events and long-term efficacy, approval requires Zepatier to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Zepatier is recommended in those who meet one of the following:

FDA-Approved Indications

52. Chronic Hepatitis C Virus (HCV) Genotype 1a. Approve for the duration noted if the patient meets the following (A, B, and C):

- A) Patient meets ONE of the following (i or ii):
 - i. Patient is ≥ 12 years of age; OR
 - ii. Patient weighs ≥ 30 kg; AND
- B) Patient meets ONE of the following (i or ii):
 - i. Approve for 12 weeks if the patient meets ONE of the following (a or b):
 - a) Patient meets both of the following [(1) and (2)]:
 - (1) Patient is treatment-naïve, OR patient has previously been treated with pegylated interferon + ribavirin *only*; AND
 - (2) Patient does NOT have a baseline NS5A polymorphism at ONE (or more) of the following the amino acid positions: 28, 30, 31, or 93; OR
 - b) Patient meets both of the following [(1) and (2)]:
 - (1) Patient has previously been treated with pegylated interferon + ribavirin and an HCV protease inhibitor; AND
 - (2) The medication will be prescribed in combination with ribavirin; OR
 - ii. Approve for 16 weeks if the patient meets the following (a, b, and c):
 - a) Patient meets one of the following [(1) or (2)]:
 - (1) Patient is treatment-naïve; OR
 - (2) Patient has previously been treated with pegylated interferon + ribavirin *only*; AND
 - b) Patient has a baseline NS5A polymorphism at ONE (or more) of the following amino acid positions: 28, 30, 31, or 93; AND
 - c) The medication will be prescribed in combination with ribavirin; AND
- C) The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, infectious diseases physician, or a liver transplant physician.

53. Chronic Hepatitis C Virus (HCV) Genotype 1b. Approve for 12 weeks if the patient meets the following (A, B, and C):

- A) Patient meets ONE of the following (i or ii):
 - i. Patient is ≥ 12 years of age; OR
 - ii. Patient weighs ≥ 30 kg; AND
- B) Patient meets ONE of the following (i or ii):
 - i. Patient meets one of the following (a or b):
 - a) Patient is treatment-naïve; OR
 - b) Patient has previously been treated with pegylated interferon + ribavirin *only*; OR
 - ii. Patient meets the following (a and b):

02/14/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- a) Patient has previously been treated with pegylated interferon + ribavirin + an HCV protease inhibitor; AND
- b) The medication will be prescribed in combination with ribavirin; AND
- C) The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, infectious diseases physician, or a liver transplant physician.

54. Chronic Hepatitis C Virus (HCV) Genotype 4. Approve for the duration noted if the patient meets the following (A, B, and C):

- A) Patient meets ONE of the following (i or ii):
 - i. Patient is ≥ 12 years of age; OR
 - ii. Patient weighs ≥ 30 kg; AND
- B) Patient meets ONE of the following (i or ii):
 - i. Patient is treatment-naïve: Approve for 12 weeks; OR
 - ii. Approve for 16 weeks if the patient meets both of the following (a and b):
 - a) Patient has previously been treated with pegylated interferon and ribavirin; AND
 - b) The medication will be prescribed in combination with ribavirin; AND
- C) The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, infectious diseases physician, or a liver transplant physician.

Other Uses with Supportive Evidence

55. Patient is Currently Receiving Zepatier. Approve for an indication or condition addressed as an approval in the Recommended Authorization Criteria section (FDA-Approved Indications). Approve the duration described above to complete a course of therapy (e.g., a patient who should receive 12 weeks and has received 3 weeks should be approved for 9 weeks to complete their 12-week course).

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Zepatier is not recommended in the following situations:

1. **Hepatitis C Virus (HCV), Child-Pugh Class B or Child-Pugh Class C Liver Disease (Moderate or Severe Hepatic Impairment).** Zepatier is contraindicated in patients with moderate or severe hepatic impairment (Child-Pugh Class B or C).¹
2. **Hepatitis C Virus (HCV) [Any Genotype], Combination with Any Other Direct-Acting Antivirals (Not Including Ribavirin).** Zepatier provides a complete antiviral regimen for patients with genotype 1 and 4 chronic HCV.
3. **Pediatric Patients (Age < 12 Years or < 30 kg).** The safety and efficacy of Zepatier have not been established in pediatric patients < 12 years of age or < 30 kg.¹ Guidelines recommend Harvoni (ledipasvir/sofosbuvir tablets) in pediatric patients with genotypes 1 or 4 chronic HCV.²
4. **Retreatment with Zepatier in Patients Who Have Previously Received Zepatier.** Zepatier is not recommended. This includes retreatment in prior null responders, prior partial responders, prior relapse patients, and patients who have not completed a course of therapy due to an adverse reaction or for other reasons.
5. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hepatology – Givlaari Prior Authorization Policy

- Givlaari™ (givosiran subcutaneous injection – Alnylam)

REVIEW DATE: 10/16/2024

OVERVIEW

Givlaari, an aminolevulinate synthase 1-directed small interfering RNA, is indicated for the treatment of **acute hepatic porphyria (AHP)** in patients ≥ 18 years of age.¹

Givlaari is a double-stranded small interfering RNA that causes degradation of aminolevulinate synthase 1 (ALAS1) mRNA in hepatocytes through RNA interference, reducing the elevated levels of liver ALAS1 mRNA.¹ This leads to reduced circulating levels of neurotoxic intermediates aminolevulinic acid and porphobilinogen, factors associated with attacks and other disease manifestations of AHP. In the pivotal trial, inclusion criteria specified a minimum of two porphyria attacks requiring hospitalization, urgent healthcare visit, or intravenous hemin administration at home in the 6 months prior to study entry. Hemin use during the study was permitted for the treatment of acute porphyria attacks.

Disease Overview

Porphyria is a group of metabolic disorders caused by abnormalities in the chemical steps that lead to the production of heme.² AHPs are a subgroup of porphyrias in which the enzyme deficiency occurs within the liver.³ AHPs include acute intermittent porphyria (AIP), variegate porphyria (VP), 5-aminolevulinic acid dehydratase deficiency porphyria (ALAD), and hereditary coproporphyria (HCP) and are characterized by acute neurovisceral symptoms with or without cutaneous manifestations.^{3,4} Symptoms and treatments for AIP, VP, ALAD, and HCP are similar; however, VP and HCP patients often develop photosensitivity. Signs and symptoms of AHP usually occur intermittently and include abdominal pain, constipation, muscle weakness, pain in the arms and legs, insomnia, emotional complications, rapid pulse, and high blood pressure. Although most symptomatic patients with AHP have complete resolution of their symptoms between attacks, those with numerous recurrences may develop chronic pain.

Dosing Information

The recommended dose is 2.5 mg/kg administered by subcutaneous injection once monthly by a healthcare professional only.

Guidelines

The Porphyrias Consortium of the National Institutes of Health's Rare Diseases Clinical Research Network has developed recommendations for evaluation and long-term management of AHPs (2017).⁵ Initial assessments should include diagnostic confirmation by biochemical testing, subsequent genetic testing to determine the specific AHP, and a complete medical history and physical examination. Preventative measures should be taken to prevent attacks. Hemin therapy (e.g., Panhematin® [hemin injection for intravenous infusion]) is recommended for preventative management in AHP and treatment during acute attacks. Patients with $\geq$ four attacks per year are candidates for either prophylactic or “on demand” infusions. The need for ongoing prophylaxis should be assessed every 6 to 12 months. Repeated long-term treatment with hemin therapy can lead to iron overload and contribute to hepatic damage and fibrosis. Carbohydrate loading (glucose tablets or dextrose solutions) has been used in early stages of an acute attack, but there are no clear data showing a benefit. Women with AHP can develop cyclic attacks correlated with the menstrual cycle. Options to prevent these attacks include recognizing and removing exacerbating

factors, a gonadotropin releasing-hormone analog, switching to a low dose hormonal contraceptive, or prophylactic hemin therapy infusions.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Givlaari. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Givlaari as well as the monitoring required for adverse events and long-term efficacy, approval requires Givlaari to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Givlaari is recommended in those who meet the following criteria:

FDA-Approved Indication

56. Acute Hepatic Porphyria. Approve for 1 year if the patient meets ALL of the following (A, B, C, and D):

- A)** Patient is ≥ 18 years of age; AND
- B)** Diagnosis of acute hepatic porphyria was confirmed by BOTH of the following (i and ii):
 - i.** Patient demonstrated clinical features associated with acute hepatic porphyria; AND
Note: Examples of clinical features associated with acute intermittent porphyria include neurovisceral symptoms, blistering lesions, hepatic involvement, peripheral neuropathy, abdominal pain, constipation, muscle weakness, pain in the arms and legs.
 - ii.** Patient meets ONE of the following (a or b):
 - a)** Elevated urinary aminolevulinic acid (ALA) greater than the upper limit of normal; OR
 - b)** Elevated urinary porphobilinogen (PBG) greater than the upper limit of normal; AND
- C)** Prior to starting treatment with Givlaari, the patient has a of one porphyria attack in the last 6 months that required a hospitalization, urgent healthcare visit, or intravenous hemin administration at home; AND
- D)** The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, or a physician who specializes in acute hepatic porphyria.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Givlaari is not recommended in the following situations:

174. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hepatology – Iqirvo Prior Authorization Policy

- Iqirvo™ (elafibranor tablets – Ipsen)

REVIEW DATE: 06/12/2024

OVERVIEW

Iqirvo, a peroxisome proliferator-activated receptor (PPAR) agonist, is indicated for the treatment of primary biliary cholangitis (PBC) in combination with ursodeoxycholic acid (UDCA) in adults with an inadequate response to UDCA, or as monotherapy in adults unable to tolerate UDCA.¹

Iqirvo was approved under accelerated approval based on reduction in alkaline phosphatase (ALP). An improvement in survival or liver decompensation events has not been established. Continued approval for this indication may be contingent upon verification and description of clinical benefit in confirmatory trials.

Limitation of use:

Iqirvo is not recommended in patients who have or develop decompensated cirrhosis (e.g., ascites, variceal bleeding, hepatic encephalopathy).

Guidelines

The American Association for the Study of Liver Diseases (AASLD) guidelines for primary biliary cholangitis (2018) state that the diagnosis can be confirmed when patients meet two of the following criteria: 1) there is cholestasis as evidenced by alkaline phosphatase elevation; 2) anti-mitochondrial antibodies are present, or if negative for anti-mitochondrial antibodies, other primary biliary cholangitis-specific autoantibodies, including sp100 or gp210, are present; 3) there is histologic evidence of nonsuppurative destructive cholangitis and destruction of interlobular bile ducts. It is specifically noted that diagnosis in a patient who is negative for anti-mitochondrial antibodies does not require a liver biopsy if other diagnostic criteria are met.² Treatment with UDCA (available in the US as ursodiol) is the recommended treatment for patients with primary biliary cholangitis who have abnormal liver enzyme values regardless of histologic stage. Following 12 months of UDCA therapy, the patient should be evaluated to determine if second-line therapy is appropriate. It is estimated that up to 40% of patients have an inadequate response to UDCA; Ocaliva® (obeticholic acid tablets), a farnesoid X receptor agonist, should be considered for these patients. An update to the 2018 AASLD guidelines for primary biliary cholangitis (2021) provide two updated recommendations:³ 1) Fibrates can be considered as off-label alternatives for patients with primary biliary cholangitis and inadequate response to UDCA. However, fibrates are discouraged in patients with decompensated liver disease; and 2) Ocaliva is contraindicated in patients with advanced cirrhosis, defined as cirrhosis with current or prior evidence of liver decompensation (e.g., encephalopathy, coagulopathy) or portal hypertension (e.g., ascites, gastroesophageal varices, or persistent thrombocytopenia). In addition, the AASLD recommends careful monitoring of any patient with cirrhosis, even if not advanced, receiving Ocaliva.

Safety

The safety and efficacy of Iqirvo in patients with decompensated cirrhosis have not been established.¹ Use of Iqirvo is not recommended in patients who have or develop decompensated cirrhosis (e.g., ascites, variceal bleeding, hepatic encephalopathy). Patients with cirrhosis should be monitored for evidence of decompensation. Consider discontinuing Iqirvo if the patient progresses to moderate or severe hepatic impairment (Child-Pugh B or C).

06/12/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Iqirvo. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Iqirvo as well as the monitoring required for adverse events and long-term efficacy, approval requires Iqirvo to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Iqirvo is recommended in those who meet the following criteria:

FDA-Approved Indication

49. Primary Biliary Cholangitis. Approve Iqirvo for the duration noted if the patient meets ONE of the following (A or B):

Note: Primary Biliary Cholangitis is also known as Primary Biliary Cirrhosis.

19. Initial Therapy. Approve for 6 months if the patient meets ALL of the following (i, ii, iii, iv, and v):

- i. Patient is ≥ 18 years of age; AND
- ii. According to the prescriber, the patient has a diagnosis of primary biliary cholangitis as defined by TWO of the following (a, b, or c):
 - a) Alkaline phosphatase is elevated above the upper limit of normal as defined by normal laboratory reference values; OR
 - b) Positive anti-mitochondrial antibodies or other primary biliary cholangitis-specific auto-antibodies, including sp100 or gp210, if anti-mitochondrial antibodies are negative; OR
 - c) Histologic evidence of primary biliary cholangitis from a liver biopsy; AND
- iii. Patient meets ONE of the following (a or b):
 - a) Patient has been receiving ursodiol therapy for ≥ 1 year and has had an inadequate response according to the prescriber; OR
 - b) According to the prescriber the patient is unable to tolerate ursodiol therapy; AND
Note: Examples of ursodiol therapy include ursodiol generic tablets and capsules, Urso 250, Urso Forte, and Actigall.
- iv. Patient does not currently have, or have a history of, a hepatic decompensation event.
Note: Examples of hepatic decompensation include ascites, gastroesophageal varices, variceal bleeding, hepatic encephalopathy, and coagulopathy.
- v. The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, or liver transplant physician.

20. Patient is Currently Receiving Therapy. Approve for 1 year if the patient meets BOTH of the following (i and ii):

- i. Patient does not currently have, or have a history of, a hepatic decompensation event.
Note: Examples of hepatic decompensation include ascites, gastroesophageal varices, variceal bleeding, hepatic encephalopathy, and coagulopathy.
- ii. Patient has demonstrated a response to therapy as determined by the prescriber.
Note: Examples of a response to therapy are improved biochemical markers of primary biliary cholangitis (e.g., alkaline phosphatase [ALP], bilirubin, gamma-glutamyl transpeptidase [GGT], aspartate aminotransferase [AST], alanine aminotransferase [ALT]).

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Iqirvo is not recommended in the following situations:

28. **Alcoholic Liver Disease.** There are no data available to support the use of Iqirvo in patients with alcoholic hepatitis.
29. **Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD)/Nonalcoholic Fatty Liver Disease (NAFLD), including Metabolic Dysfunction-Associated Steatohepatitis (MASH)/Non-Alcoholic Steatohepatitis (NASH).** In a Phase III trial (RESOLVE-IT) of Iqirvo in adults with MASH and fibrosis, Iqirvo did not demonstrate a statistically significant effect on the primary endpoint of NASH resolution without worsening of fibrosis.⁴ The response rate in the 717 patients enrolled was 19.2% for patients who received Iqirvo compared to 14.7% for patients in the placebo arm. Additionally, no significant differences as compared to placebo were achieved in the key secondary endpoints, including fibrosis improvement of at least one stage and changes in metabolic parameters.
30. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hepatology – Livdelzi Prior Authorization Policy

- Livdelzi™ (seladelpar capsules – Gilead)

REVIEW DATE: 08/15/2024

OVERVIEW

Livdelzi, a peroxisome proliferator-activated receptor (PPAR)-delta agonist, is indicated for the treatment of primary biliary cholangitis (PBC) in combination with ursodeoxycholic acid (UDCA) in adults with an inadequate response to UDCA, or as monotherapy in adults unable to tolerate UDCA.¹

Livdelzi was approved under accelerated approval based on reduction in alkaline phosphatase (ALP).¹ An improvement in survival or liver decompensation events has not been established. Continued approval for this indication may be contingent upon verification and description of clinical benefit in confirmatory trials.

Limitation of use:

Livdelzi is not recommended in patients who have or develop decompensated cirrhosis (e.g., ascites, variceal bleeding, hepatic encephalopathy).

Guidelines

The American Association for the Study of Liver Diseases (AASLD) guidelines for primary biliary cholangitis (2018) state that the diagnosis can be confirmed when patients meet two of the following criteria: 1) there is cholestasis as evidenced by alkaline phosphatase elevation; 2) anti-mitochondrial antibodies are present, or if negative for anti-mitochondrial antibodies, other primary biliary cholangitis-specific autoantibodies, including sp100 or gp210, are present; 3) there is histologic evidence of nonsuppurative destructive cholangitis and destruction of interlobular bile ducts. It is specifically noted that diagnosis in a patient who is negative for anti-mitochondrial antibodies does not require a liver biopsy if other diagnostic criteria are met.² Treatment with UDCA (available in the US as ursodiol) is the recommended treatment for patients with primary biliary cholangitis who have abnormal liver enzyme values regardless of histologic stage. Following 12 months of UDCA therapy, the patient should be evaluated to determine if second-line therapy is appropriate. It is estimated that up to 40% of patients have an inadequate response to UDCA; Ocaliva® (obeticholic acid tablets), a farnesoid X receptor agonist, should be considered for these patients. An update to the 2018 AASLD guidelines for primary biliary cholangitis (2021) provide two updated recommendations:³ 1) Fibrates can be considered as off-label alternatives for patients with primary biliary cholangitis and inadequate response to UDCA. Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Livdelzi is recommended in those who meet the following criteria:

FDA-Approved Indication

50. Primary Biliary Cholangitis. Approve for the duration noted if the patient meets ONE of the following (A or B):

Note: Primary Biliary Cholangitis is also known as Primary Biliary Cirrhosis.

21. Initial Therapy. Approve for 6 months if the patient meets ALL of the following (i, ii, iii, iv, and v):

- i. Patient is ≥ 18 years of age; AND
- ii. According to the prescriber, the patient has a diagnosis of primary biliary cholangitis as defined by TWO of the following (a, b, or c):
 - a) Alkaline phosphatase is elevated above the upper limit of normal as defined by normal laboratory reference values; OR
 - b) Positive anti-mitochondrial antibodies or other primary biliary cholangitis-specific auto-antibodies, including sp100 or gp210, if anti-mitochondrial antibodies are negative; OR
 - c) Histologic evidence of primary biliary cholangitis from a liver biopsy; AND
- iii. Patient meets ONE of the following (a or b):
 - a) Patient has been receiving ursodiol therapy for ≥ 1 year and has had an inadequate response according to the prescriber; OR
 - b) According to the prescriber the patient is unable to tolerate ursodiol therapy; AND
Note: Examples of ursodiol therapy include ursodiol generic tablets and capsules, Urso 250, Urso Forte, and Actigall.
- iv. Patient does not currently have, or have a history of, a hepatic decompensation event; AND
Note: Examples of hepatic decompensation include ascites, gastroesophageal varices, variceal bleeding, hepatic encephalopathy, and coagulopathy.
- v. The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, or liver transplant physician.

22. Patient is Currently Receiving Therapy. Approve for 1 year if the patient meets BOTH of the following (i and ii):

- i. Patient does not currently have, or have a of, a hepatic decompensation event.
Note: Examples of hepatic decompensation include ascites, gastroesophageal varices, variceal bleeding, hepatic encephalopathy, and coagulopathy.
- ii. Patient has demonstrated a response to therapy as determined by the prescriber.

Note: Examples of a response to therapy are improved biochemical markers of primary biliary cholangitis (e.g., alkaline phosphatase [ALP], bilirubin, gamma-glutamyl transpeptidase [GGT], aspartate aminotransferase [AST], alanine aminotransferase [ALT]).

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Livdelzi is not recommended in the following situations:

- 31. Alcoholic Liver Disease.** There are no data available to support the use of Livdelzi in patients with alcoholic hepatitis.
- 32. Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD)/Nonalcoholic Fatty Liver Disease (NAFLD), including Metabolic Dysfunction-Associated Steatohepatitis (MASH)/Non-Alcoholic Steatohepatitis (NASH).** There is not sufficient data available to support the use of Livdelzi in patients with MASLD/NAFLD. Clinical development of Livdelzi for MASH was halted after liver biopsies of some patients had shown evidence of interface hepatitis.⁴ Although an independent panel of hepatologists and pathologists concluded there was no chemical, biochemical, or histological evidence this was attributed to active treatment, resumption of the clinical program was not pursued.
- 33. Concomitant use with Ocaliva (obeticholic acid tablets) or Iqirvo (elafibranor tablets).** There are no data available to support the use of Livdelzi in combination with Ocaliva or Iqirvo in patients with PBC.
- 34.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hepatology – Livmarli Prior Authorization Policy

- Livmarli™ (maralixibat oral solution – Mirum)

REVIEW DATE: 10/16/2024

OVERVIEW

Livmarli, an ileal bile acid transporter (IBAT) inhibitor, is indicated for the treatment of:¹

- Cholestatic pruritus in patients ≥ 3 months of age with **Alagille syndrome** (ALGS).
- Cholestatic pruritus in patients ≥ 12 months of age with **progressive familial intrahepatic cholestasis** (PFIC).

Disease Overview

ALGS is a rare liver disease defined by genetic deletion or genetic pathogenic variants affecting bile acid transporters (e.g., deletion or variant of the *JAG1* gene or *NOTCH2* gene).²⁻⁴ **PFIC** is a group of rare, autosomal recessive liver diseases defined by genetic pathogenic variants affecting bile acid transporters (e.g., variants of the *ATP8B1* gene, *ABCB11* gene, *ABCB4* gene, *TJP2* gene, *NR1H4* gene, or *MYO5B* gene).⁵⁻⁷ Progression of both diseases can cause liver fibrosis, cirrhosis, or end-stage liver disease and leads to death at an early age in life (infancy to adolescence).

Cholestasis, jaundice, and pruritus are common symptoms in patients with PFIC and ALGS.^{2,5} Although the complete mechanism by which Livmarli improves pruritus in these patients is unknown, it may involve inhibition of the IBAT, which results in decreased reuptake of bile salts, as observed by a decrease in serum bile acids.¹ Cholestyramine, rifampicin, and ursodeoxycholic acid (ursodiol) have been used off-label for decades to alleviate symptoms related to PFIC and ALGS.⁷⁻⁹ Cholestyramine, ursodeoxycholic acid, rifampicin, naltrexone, and sertraline are recommended in clinical practice guidelines from the European Association for the Study of the Liver (2009).

Clinical Efficacy

The efficacy of Livmarli for ALGS was evaluated in one study that included an 18-week open-label treatment period, followed by a 4-week randomized, double-blind, placebo-controlled drug withdrawal period.¹ The study was conducted in 31 pediatric patients with ALGS (1 year to 15 years of age) with cholestasis and pruritus. All enrolled patients had a *JAG1* genetic variant, elevated serum bile acid concentration, and presence of at least moderate pruritus at baseline. Approximately 90.3% of patients were receiving at least one medication to treat pruritus at study entry. Patients treated with Livmarli demonstrated greater improvement in pruritus compared to placebo. Safety and tolerability in infants less than 1 year of age was assessed in a 13-week, open label, phase II study of 12 patients. Livmarli was well-tolerated with treatment emergent adverse events, which were mostly Grade 1 and unrelated to therapy.

The efficacy of Livmarli for PFIC was evaluated in one 26-week, randomized, placebo-controlled pivotal trial.¹ Efficacy was evaluated in 64 patients (12 months to 17 years of age) with a clinical genetic confirmation of PFIC. Patients had to have an elevated serum bile acid concentration along with presence of moderate to severe pruritus at baseline. Most patients were on stable ursodeoxycholic acid (89.1%) or rifampicin (51.6%) therapy at baseline. Patients treated with Livmarli demonstrated greater improvement in pruritus compared with placebo.

10/16/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Safety

Livmarli was not evaluated in patients with decompensated cirrhosis.¹ Monitor for liver test abnormalities; permanently discontinue Livmarli if a patient progresses to portal hypertension or experiences a hepatic decompensation event (e.g., variceal hemorrhage, ascites, hepatic encephalopathy).

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Livmarli. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Livmarli as well as the monitoring required for adverse events and long-term efficacy, approval requires Livmarli to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Livmarli is recommended in those who meet one of the following criteria:

FDA-Approved Indications

57. Alagille Syndrome. Approve for the duration noted if the patient meets ONE of the following (A or B):

A) Initial Therapy. Approve for 6 months if the patient meets ALL of the following (i, ii, iii, iv, v, vi and vii):

- i.** Patient is ≥ 3 months of age; AND
- ii.** Patient has moderate-to-severe pruritus, according to the prescriber; AND
- iii.** Diagnosis of Alagille syndrome was confirmed by genetic testing demonstrating a *JAG1* or *NOTCH2* deletion or pathogenic variant; AND
- iv.** Patient has a serum bile acid concentration above the upper limit of the normal reference range for the reporting laboratory; AND
- v.** Patient has tried at least two systemic medications for Alagille syndrome, unless contraindicated; AND

Note: Systemic medications for Alagille syndrome include cholestyramine, naltrexone, rifampicin, sertraline, and ursodeoxycholic acid (ursodiol).

vi. Patient does not have any of the following (a, b, or c):

- a)** Cirrhosis; OR
- b)** Portal hypertension; OR
- c)** History of a hepatic decompensation event; AND

Note: Examples of a hepatic decompensation event include variceal hemorrhage, ascites, and hepatic encephalopathy.

vii. The medication is prescribed by or in consultation with a hepatologist, gastroenterologist, or a physician who specializes in Alagille syndrome.

B) Patient is Currently Receiving Livmarli. Approve for 1 year if the patient meets ALL of the following (i, ii, and iii):

i. Patient does not have any of the following (a, b, or c):

- a)** Cirrhosis; OR
- b)** Portal hypertension; OR
- c)** History of a hepatic decompensation event; AND

Note: Examples of a hepatic decompensation event include variceal hemorrhage, ascites, and hepatic encephalopathy.

- ii. Patient had response to therapy, as determined by the prescriber; AND

Note: Examples of response to therapy include decrease in serum bile acids and decrease in pruritus.

- iii. The medication is prescribed by or in consultation with a hepatologist, gastroenterologist, or a physician who specializes in Alagille syndrome.

58. Progressive Familial Intrahepatic Cholestasis. Approve for the duration noted if the patient meets ONE of the following (A or B):

A) Initial Therapy. Approve for 6 months if the patient meets ALL of the following (i, ii, iii, iv, v, vi and vii):

- i. Patient is ≥ 12 months of age; AND

- ii. Patient has moderate-to-severe pruritus, according to the prescriber; AND

- iii. Diagnosis of progressive familial intrahepatic cholestasis was confirmed by genetic testing demonstrating a pathogenic gene variant affiliated with progressive familial intrahepatic cholestasis; AND

Note: Gene variants affiliated with progressive familial intrahepatic cholestasis include the *ATP8B1* gene, *ABCB11* gene, *ABCB4* gene, *TJP2* gene, *NR1H4* gene, and *MYO5B* gene.

- iv. Patient has a serum bile acid concentration above the upper limit of the normal reference range for the reporting laboratory; AND

- v. Patient has tried at least two systemic medications for progressive familial intrahepatic cholestasis, unless contraindicated; AND

Note: Systemic medications for progressive familial intrahepatic cholestasis include cholestyramine, naltrexone, rifampicin, sertraline, and ursodeoxycholic acid (ursodiol).

- vi. Patient does not have any of the following (a, b, or c):

- a) Cirrhosis; OR

- b) Portal hypertension; OR

- c) History of a hepatic decompensation event; AND

Note: Examples of a hepatic decompensation event include variceal hemorrhage, ascites, and hepatic encephalopathy.

- vii. The medication is prescribed by or in consultation with a hepatologist, gastroenterologist, or a physician who specializes in progressive familial intrahepatic cholestasis.

B) Patient is Currently Receiving Livmarli. Approve for 1 year if the patient meets ALL of the following (i, ii, and iii):

- i. Patient does not have any of the following (a, b, or c):

- a) Cirrhosis; OR

- b) Portal hypertension; OR

- c) of a hepatic decompensation event; AND

Note: Examples of a hepatic decompensation event include variceal hemorrhage, ascites, and hepatic encephalopathy.

- ii. Patient had response to therapy, as determined by the prescriber; AND

Note: Examples of response to therapy include decrease in serum bile acids and decrease in pruritus.

- iii. The medication is prescribed by or in consultation with a hepatologist, gastroenterologist, or a physician who specializes in progressive familial intrahepatic cholestasis.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Livmarli is not recommended in the following situations:

175. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hepatology – Ocaliva Prior Authorization Policy

- Ocaliva® (obeticholic acid tablets – Intercept Pharmaceuticals)

REVIEW DATE: 07/24/2024

OVERVIEW

Ocaliva, a farnesoid X receptor agonist, is indicated for the treatment of **primary biliary cholangitis** in adults without cirrhosis, or with compensated cirrhosis who do not have evidence of portal hypertension.¹ It is specifically indicated to be given either in combination with ursodeoxycholic acid (UDCA) in adults with an inadequate response to UDCA or as monotherapy in adults unable to tolerate UDCA.

Guidelines

The American Association for the Study of Liver Diseases (AASLD) guidelines for primary biliary cholangitis (2018) state that the diagnosis can be confirmed when patients meet two of the following criteria: 1) there is cholestasis as evidenced by alkaline phosphatase elevation; 2) anti-mitochondrial antibodies are present, or if negative for anti-mitochondrial antibodies, other primary biliary cholangitis-specific autoantibodies, including sp100 or gp210, are present; 3) there is histologic evidence of nonsuppurative destructive cholangitis and destruction of interlobular bile ducts. It is specifically noted that diagnosis in a patient who is negative for anti-mitochondrial antibodies does not require a liver biopsy if other diagnostic criteria are met.⁴ Treatment with UDCA (available in the US as ursodiol) is the recommended treatment for patients with primary biliary cholangitis who have abnormal liver enzyme values regardless of histologic stage.³ Following 12 months of UDCA therapy, the patient should be evaluated to determine if second-line therapy is appropriate. It is estimated that up to 40% of patients have an inadequate response to UDCA; Ocaliva should be considered for these patients. An update to the 2018 AASLD guidelines for primary biliary cholangitis (2021) provide two updated recommendations:⁹ 1) Fibrates can be considered as off-label alternatives for patients with primary biliary cholangitis and inadequate response to UDCA. However, fibrates are discouraged in patients with decompensated liver disease; and 2) Ocaliva is contraindicated in patients with advanced cirrhosis, defined as cirrhosis with current or prior evidence of liver decompensation (e.g., encephalopathy, coagulopathy) or portal hypertension (e.g., ascites, gastroesophageal varices, or persistent thrombocytopenia). In addition, the AASLD recommends careful monitoring of any patient with cirrhosis, even if not advanced, receiving Ocaliva.

The European Association for the Study of the Liver guidelines for diagnosis and management of patients with primary biliary cholangitis (2017) make similar recommendations.⁷

Safety

Ocaliva has a Boxed warning regarding hepatic decompensation and failure in patients with primary biliary cholangitis and cirrhosis.¹ Ocaliva is contraindicated in patients with primary biliary cholangitis with decompensated cirrhosis and patients with a prior decompensation event. It is also contraindicated in patients with compensated cirrhosis with evidence of portal hypertension (e.g., ascites, gastroesophageal varices, and persistent thrombocytopenia) as well as those with complete biliary obstruction.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Ocaliva. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Ocaliva as well as the monitoring required for adverse events and long-term efficacy, approval requires Ocaliva to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Ocaliva is recommended in those who meet the following criteria:

FDA-Approved Indication

51. Primary Biliary Cholangitis. Approve Ocaliva for the duration noted if the patient meets ONE of the following (A or B):

Note: Primary Biliary Cholangitis is also known as Primary Biliary Cirrhosis.

23. Initial Therapy. Approve for 6 months if the patient meets ALL of the following (i, ii, iii, and iv):

- i. Patient is ≥ 18 years of age; AND
- ii. According to the prescriber, the patient has a diagnosis of primary biliary cholangitis as defined by TWO of the following (TWO of a, b, or c):
 - a) Alkaline phosphatase is elevated above the upper limit of normal as defined by normal laboratory reference values; OR
 - b) Positive anti-mitochondrial antibodies or other primary biliary cholangitis-specific auto-antibodies, including sp100 or gp210, if anti-mitochondrial antibodies are negative; OR
 - c) Histologic evidence of primary biliary cholangitis from a liver biopsy; AND
- iii. Patient meets ONE of the following (a or b):
 - a) Patient has been receiving ursodiol therapy for ≥ 1 year and has had an inadequate response according to the prescriber; OR
 - b) According to the prescriber the patient is unable to tolerate ursodiol therapy; AND
Note: Examples of ursodiol therapy include ursodiol generic tablets and capsules, Urso 250, Urso Forte, and Actigall.
- iv. Patient meets ONE of the following (a or b):
 - a) Patient does not have cirrhosis; OR
 - b) Patient has compensated cirrhosis without evidence of portal hypertension; AND
Note: Examples of evidence of portal hypertension include ascites, gastroesophageal varices, and persistent thrombocytopenia. Ocaliva is contraindicated in these patients.
- v. The medication is prescribed by or in consultation with a gastroenterologist, hepatologist, or liver transplant physician.

24. Patient is Currently Receiving Therapy. Approve for 1 year if the patient meets BOTH of the following (i and ii):

- i. Patient meets ONE of the following (a or b):
 - a) Patient does not have cirrhosis; OR
 - b) Patient has compensated cirrhosis without evidence of portal hypertension; AND
Note: Examples of evidence of portal hypertension include ascites, gastroesophageal varices, and persistent thrombocytopenia. Ocaliva is contraindicated in these patients.
- ii. Patient has responded to Ocaliva as determined by the prescriber.

Note: Examples of a response to Ocaliva therapy are improved biochemical markers of primary biliary cholangitis (e.g., alkaline phosphatase [ALP], bilirubin, gamma-glutamyl transpeptidase [GGT], aspartate aminotransferase [AST], alanine aminotransferase [ALT]).

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Ocaliva is not recommended in the following situations:

35. **Alcoholic Liver Disease.** There are no data available to support the use of Ocaliva in patients with alcoholic hepatitis. Ocaliva is not FDA-approved for this indication and current alcoholic liver disease guidelines from AASLD (2019) do not make recommendations regarding therapy with Ocaliva.^{1,8} Additional well-controlled studies are needed.
36. **Nonalcoholic Fatty Liver Disease (NAFLD), including Nonalcoholic Fatty Liver (NAFL) or Nonalcoholic Steatohepatitis (NASH).** Ocaliva is not FDA-approved for this indication and current NAFLD guidelines from AASLD (2023) do not recommend the off-label use of obeticholic acid to treat NASH until additional safety and efficacy data become available.^{1,8}
37. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hepatology – Rezdiffra Prior Authorization Policy

- Rezdiffra™ (resmetirom tablets – Madrigal Pharmaceuticals)

REVIEW DATE: 04/03/2024; selected revision 05/08/2024 and 12/04/2024

OVERVIEW

Rezdiffra, a thyroid hormone receptor-beta (THR- β) agonist, is indicated in combination with diet and exercise for the treatment of **non-cirrhotic non-alcoholic steatohepatitis (NASH)** with moderate to advanced liver fibrosis (consistent with stages F2 to F3 fibrosis) in adults.¹ Limitations of Use: Avoid use in patients with decompensated cirrhosis.

This indication is approved under accelerated approval based on improvement of NASH and fibrosis. Continued approval for this indication may be contingent upon verification and description of clinical benefit in confirmatory trial.¹

Disease Overview

NASH, also known as metabolic-dysfunction associated steatohepatitis (MASH), is a progressive liver disease characterized by the presence of $\geq 5\%$ hepatic steatosis with hepatocellular damage and inflammation in the absence of readily identified alternative cause of steatosis (e.g., medications, starvation, monogenic disorders) in individuals who drink little or no alcohol (defined as < 20 g/day for women and < 30 g/day for men).² Once NASH progresses to clinically meaningful fibrosis (stages F2 and F3), the risk of adverse clinical outcomes increases. In the US, it is estimated that 1.5% to 6.5% of adults have NASH.³ The estimated prevalence of high-risk NASH (defined as non-alcoholic fatty liver disease activity score [NAS] ≥ 4 and fibrosis stage ≥ 2 [F2]) in the US is 5.8%. The risk of NASH is two- to three-fold higher in individuals with obesity (25% to 30%) and/or type 2 diabetes (30% to 40%).⁴ In the US, NASH is among the top causes of hepatocellular carcinoma and the second most common indication for liver transplantation after hepatitis C.

Clinical Efficacy

The efficacy of Rezdiffra was evaluated in one ongoing, Phase III, randomized, double-blind, placebo-controlled, multicenter, pivotal study in adults with biopsy-confirmed NASH (MAESTRO-NASH) with fibrosis (F1B, F2, or F3) [n = 966].⁵ The dual primary endpoints at Week 52 were 1) NASH resolution (achievement of a hepatocellular ballooning score = 0, inflammation score = 0 or 1, and ≥ 2 point reduction in non-alcoholic fatty liver disease activity score [NAS]) with no worsening of fibrosis, and 2) ≥ 1 stage improvement in fibrosis with no worsening of NAS. The key secondary endpoint was the percent reduction in low-density lipoprotein cholesterol (LDL-C) at Week 24. Patients who reached the Week 52 analysis were eligible to continue to the open-label extension with a primary endpoint of a composite of all-cause mortality, liver transplant, and significant hepatic events (including hepatic decompensation events [ascites, encephalopathy, or variceal hemorrhage], histological progression to cirrhosis, and a confirmed increase of modified end-stage liver disease [MELD] score from < 12 to ≥ 15). Eligible patients were ≥ 18 years of age, had at least three of five metabolic risk factors according to the International Diabetes Foundation criteria for metabolic syndrome⁹ (central obesity, elevated triglycerides [≥ 150 mg/dL], reduced high-density lipoprotein cholesterol [< 50 mg/dL in females or < 40 mg/dL in males], elevated blood pressure [$\geq 130/85$ mmHg], elevated fasting plasma glucose [≥ 100 mg/dL]), and had undergone prescreening vibration-controlled transient elastography (VCTE; FibroScan) within the past 3 months that showed a controlled attenuation parameter of ≥ 280 dB/meter and a liver stiffness measurement of ≥ 8.5 kPa.

04/03/2024

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

(alternately, a liver biopsy that was performed within 6 months before randomization could be confirmed to be eligible as a baseline biopsy by the central pathologist of the trial). Additional key inclusion criteria were histologic evidence of NASH and an NAS of ≥ 4 (on a scale of 0 to 8 with higher scores indicating more severe disease), with a score of ≥ 1 for each component (steatosis [on a scale of 0 to 3], lobular inflammation [on a scale from 0 to 3], and hepatocellular ballooning [on a scale from 0 to 2]). Key exclusion criteria were alcohol consumption of > 20 g/day for women and > 30 g/day for men for a period of ≥ 3 consecutive months within 1 year of screening and causes of chronic liver disease other than non-cirrhotic NASH.

The mean age was 57 years, the mean body mass index was 35.7 kg/m^2 , 67% of patients had type 2 diabetes, 78% of patients had hypertension, and 71% of patients had dyslipidemia (approximately 50% of patients were taking a statin).⁵ Glucagon-like receptor-1 agonist use was reported in approximately 15% of patients. Most patients had a fibrosis stage of F3 (62%), 33% of patients had F2, and 5% of patients had F1B. All patients underwent lifestyle modification consisting of diet and exercise.

At Week 52, NASH resolution associated with a ≥ 2 point reduction in NAS without worsening of fibrosis stage was reported for 29.9% and 25.9% of patients in the Rezdiffra 100 mg and 80 mg groups, respectively vs. 9.7% of patients in the placebo group ($P < 0.0001$ for Rezdiffra doses vs. placebo).⁵ The proportion of patients with ≥ 1 stage fibrosis improvement with no worsening in NAS at Week 52 was 25.9% and 24.2% for Rezdiffra 100 mg and 80 mg, respectively vs. 14.2% for placebo ($P < 0.0001$ for Rezdiffra doses vs. placebo). At Week 24, LDL-C was reduced by -16.3% and -13.6% with Rezdiffra 100 mg and 80 mg, respectively, vs. +0.7% with placebo ($P = 0.0001$ Rezdiffra doses vs. placebo) [key secondary endpoint]. Fewer patients treated with Rezdiffra vs. placebo with F1B or F2 at baseline progressed to $\geq$ F3 (18% to 19% vs. 34%, respectively) and more patients treated with Rezdiffra vs. placebo with F1B or F2 at baseline had an improved fibrosis stage (31% to 33% vs. 15%, respectively). A similar proportion of patients treated with Rezdiffra and placebo with F1B or F2 at baseline had no change (stable) in fibrosis stage at Week 52 (48% to 51% vs. 51%, respectively).

Guidelines

An update to the American Association for the Study of Liver Diseases (AASLD) Practice Guidance on the Clinical Management of non-alcoholic fatty liver disease (NAFLD) was published in October 2024 to address the approval of Rezdiffra.¹⁰ It is recognized that although MASH can only be definitively diagnosed by histologic exam (biopsy), in practice, patient selection is based on evidence of steatosis and fibrosis as determined by non-invasive liver disease assessments (NILDAs) in patients with cardiometabolic risk factors without other causes of steatosis, notably, alcohol consumption of > 20 g/day for women and > 30 g/day in men. There are no FDA-approved NILDAs to diagnose MASH with stage F2 to F3 fibrosis or to monitor the response to pharmacotherapy. In general imaging-based NILDAs such as liver stiffness measurement (LSM) by VCTE or magnetic resonance elastography (MRE) have better accuracy in assessing fibrosis vs. blood-based tests. In general, magnetic resonance spectroscopy and magnetic resonance imaging proton fat density fat fraction (MRI-PDFF) are considered the most accurate quantitative measures of hepatic steatosis, followed by VCTE-controlled attenuation parameter score and gray scale ultrasound. However, for the purpose of selecting patients for treatment with Rezdiffra, non-quantitative imaging evidence of hepatic steatosis (e.g., ultrasonographic evidence) in individuals with at least one cardiometabolic risk factor and F2 or F3 fibrosis may be sufficient. Liver biopsy is not typically recommended for fibrosis staging in current clinical practice; however, histologic exam remains the gold standard to quantify fibrosis if performed previously (historical biopsy obtained reasonably recently, e.g., within 3 years). Since NILDAs are more readily available than liver biopsy, it is recommended that more current data (e.g., within 6 to 12 months) be utilized to determine patients who are appropriate candidates for treatment with Rezdiffra. Regardless of treatment, the management of metabolic-dysfunction associated steatotic liver disease (MASLD) should include comprehensive lifestyle modification (e.g., nutrition,

exercise, and behavior modification) and optimal control of comorbid metabolic conditions. Further, given the comorbidity profile of individuals with MASLD, cardiovascular risk management is an important aspect of medical management.

When selecting appropriate patients for treatment, Rezdiffra can be considered in adults with MASH and moderate to advanced liver fibrosis (consistent with F2 or F3 fibrosis).¹⁰ The diagnosis should be assessed by one of the following: 1) NILDA, preferably imaging-based test results, consistent with MASH with stage F2 or F3 fibrosis; or 2) Historical liver biopsy demonstrating MASH with stage F2 or F3 fibrosis (and without evidence of concomitant, histologically active autoimmune liver disease). Rezdiffra is not recommended in patients with the following: compensated or decompensated cirrhosis, concomitant uncontrolled active liver diseases (e.g., autoimmune hepatitis, primary biliary cholangitis), or alcohol consumption > 20 grams/day (women) or > 30 grams/day (men), or symptomatic gallstone-related conditions (e.g., acute cholecystitis). While some values for NILDAs (VCTE and MRE) are cited within the update, for choosing patients appropriate for treatment with Rezdiffra, they are not completely aligned with the MAESTRO-NASH trials, and the AASLD notes that clinicians may consider expanded non-invasive criteria in making treatment decisions.

The updated guidance also addresses efficacy and futility of Rezdiffra treatment based on the Week 52 data with Rezdiffra from MAESTRO-NASH.¹⁰ However, it is recognized that these recommendations may change when longer-term data become available. The decision to continue treatment beyond 12 months should be based on evidence of improvement, worsening, or treatment failure, or disease stabilization. Although the guidance provides recommendations for continuing/re-evaluating treatment with Rezdiffra based on LSM values for VCTE or MRE, reliable evidence to correlate LSM data with histologic changes in liver fibrosis is lacking. Continuation of Rezdiffra in patients with significant fibrosis improvement is recommended. In patients with evidence of worsening of liver disease at Month 12, discontinuation of Rezdiffra should be considered. Worsening liver disease can be identified by clinical data suggestive of worsening liver disease including consistent increase in alanine aminotransferase or fibrosis progression as assessed by NILDA. In patients without clear evidence of liver disease improvement or worsening, the decision to continue therapy (pending longer-term data) should be based on holistic patient assessment considering baseline fibrosis status and potential benefit of slowing or stabilizing liver fibrosis even if no regression is noted; individual comorbidity profile associated with progressive liver disease; concomitant therapy including adherence and response to lifestyle interventions; changes in liver biochemical and NILDA parameters; and adverse effects (if any) during treatment with Rezdiffra.

Other available guidelines do not address Rezdiffra. The AASLD (2023), American Association of Clinical Endocrinology (2022), and American Gastroenterological Association (AGA) [2021] provide guidelines and/or guidance on the overall management of NAFLD and NASH.^{4,6,7} The goal of liver-directed treatment is to reverse steatohepatitis and fibrosis, or to at least halt the progression of fibrosis.⁷ Importantly, the presence of steatosis serves largely as a biomarker or risk factor of steatohepatitis with fibrosis; however, the presence of steatosis does not necessarily imply severe disease. In general, in patients with NASH with $\geq$ F2 fibrosis, agents approved for other indications that have shown benefit for NASH in clinical trials should be considered under specific circumstances (e.g., diabetes, obesity).^{4,6,7} A healthy diet and regular exercise are the foundation of treatment. Weight loss of $\geq$ 10% is generally required to improve NASH and fibrosis. Management of comorbid conditions (e.g., cardiovascular disease, obesity, diabetes) should be done in-line with the standard of care and encourage use of agents that have shown benefit in NASH (e.g., liraglutide, semaglutide, pioglitazone, vitamin E).

According to the AASLD, targeted screening of populations at increased risk for advanced liver disease is advised to identify and manage those with clinically significant fibrosis (stage $\geq$ F2).² The primary goal in the specialty care setting (gastroenterology, hepatology) is the identification of patients with “at-risk”

NASH or advanced fibrosis. Such patients require further assessment and may benefit from targeted interventions. The AGA recommends that at-risk patients be screened for alcohol use and have liver tests as well as a complete blood count as part of the initial screening process.⁷ Results from standard laboratory tests can allow calculation of simple fibrosis scores using non-invasive tests for fibrosis (e.g., Fibrosis-4 [FIB-4] or NAS). Patients with a FIB-4 of ≥ 1.3 to ≤ 2.67 are considered to be at indeterminate risk and should undergo an LSM, ultrasound is acceptable if VCTE (Fibroscan) is unavailable. Other methods such as bidimensional shear wave elastography or point shear wave elastography can also be used to measure LSM. If the LSM by VCTE is ≥ 8 kPa to ≤ 12 kPa, patients are considered to be at indeterminate risk, and referral to a hepatologist for liver biopsy or MRE or monitoring with re-evaluation in 2 to 3 years is recommended. Of note, an LSM of ≥ 8.0 equates to clinically significant fibrosis ($\geq$ F2); an LSM < 8.0 is considered low risk for clinically significant fibrosis and can be managed with repeat surveillance testing in 2 to 3 years. Patients with a FIB-4 > 2.67 are considered high risk and should be referred to a hepatologist. Additionally, patients with a LSM > 12 kPa or a liver biopsy showing F2 to F4 fibrosis are also considered high risk.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Rezdiffra. All approvals are provided for the duration noted below. In the clinical criteria, as appropriate, an asterisk (*) is noted next to the specified gender. In this context, the specified gender is defined as follows: males are defined as individuals with the biological traits of a male, regardless of the individual's gender identity or gender expression; females are defined as individuals with the biological traits of a female, regardless of the individual's gender identity or gender expression. Because of the specialized skills required for evaluation and diagnosis of patients treated with Rezdiffra as well as the monitoring required for adverse events and long-term efficacy, approval requires Rezdiffra to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Documentation: Documentation is required for use of Rezdiffra as noted in the criteria as **[documentation required]**. Documentation may include, but is not limited to, chart notes, laboratory results, medical test results, claims records, prescription receipts, and/or other information.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Rezdiffra is recommended in those who meet the following:

FDA-Approved Indication

59. Metabolic-Dysfunction Associated Steatohepatitis (MASH)/Non-Alcoholic Steatohepatitis (NASH), with Moderate to Advanced Liver Fibrosis. Approve for 1 year if the patient meets the ONE of the following (A or B):

- A) **Initial Therapy:** Approve if the patient meets ALL of the following (i, ii, iii, iv, v, vi, and vii):
- i. Patient is ≥ 18 years of age; AND
 - ii. Prior to treatment with Rezdiffra, the diagnosis of MASH/NASH is confirmed by ONE of the following (a or b):
 - a) Patient has had a liver biopsy AND meets BOTH of the following [(1) and (2)]:
 - (1) Liver biopsy has been performed within the 3 years preceding treatment with Rezdiffra **[documentation required]**; AND
 - (2) Liver biopsy shows non-alcoholic fatty liver disease activity score of ≥ 4 with a score of > 1 in ALL of the following ([i], [ii], and [iii]) **[documentation required]**:

- (i) Steatosis; AND
 - (ii) Ballooning; AND
 - (iii) Lobular inflammation; OR
 - b) Patient has had ONE of the following imaging exams performed within the 3 months preceding treatment with Rezdiffra [(1), (2), or (3)] **[documentation required]**:
 - (1) Elastography; OR

Note: Examples of elastography include, but are not limited to vibration-controlled transient elastography (e.g., FibroScan), transient elastography, magnetic resonance elastography, acoustic radiation force impulse imaging, shear wave elastography.
 - (2) Computed tomography; OR
 - (3) Magnetic resonance imaging; AND
 - iii. Patient meets ONE of the following prior to treatment with Rezdiffra (a or b) **[documentation required]**:
 - a) Patient has stage F2 fibrosis; OR
 - b) Patient has stage F3 fibrosis; AND
 - iv. According to the prescriber, the patient has THREE or more of the following metabolic risk factors that are managed according to standard of care (a, b, c, d, e):
 - a) Central obesity;
 - b) Hypertriglyceridemia;
 - c) Reduced high-density lipoprotein cholesterol;
 - d) Hypertension;
 - e) Elevated fasting plasma glucose indicative of diabetes or pre-diabetes; AND
 - v. According to the prescriber, patient meets ONE of the following (a or b):
 - a) Female* patient: Alcohol consumption is < 20 grams/day; OR

Note: One standard drink (or one alcoholic drink equivalent) contains roughly 14 grams of pure alcohol, which is found in 12 ounces of regular beer, 5 ounces of wine, or 1.5 ounces of distilled spirits.
 - b) Male* patient: Alcohol consumption < 30 grams/day; AND

Note: One standard drink (or one alcoholic drink equivalent) contains roughly 14 grams of pure alcohol, which is found in 12 ounces of regular beer, 5 ounces of wine, or 1.5 ounces of distilled spirits.
 - vi. The medication will be used in combination with appropriate diet and exercise therapy; AND
 - vii. The medication is prescribed by or in consultation with an endocrinologist, gastroenterologist, or hepatologist.
- B) Patient is Currently Receiving Rezdiffra:** Approve if the patient meets ALL of the following (i, ii, iii, iv, v, and vi):
- Note: A patient who has received < 1 year of therapy or who is restarting therapy should be considered under criterion A (Initial Therapy).
- i. Patient has completed ≥ 1 year of therapy with Rezdiffra AND according to the prescriber, the patient has not had worsening of fibrosis or MASH/NASH; AND

Note: This applies to a patient starting their second (or more) of therapy with Rezdiffra (i.e., the patient has already completed 1 year or more of therapy with Rezdiffra).
 - ii. According to the prescriber, patient has not progressed to stage F4 (cirrhosis); AND
 - iii. According to the prescriber, metabolic risk factors are managed according to standard of care; AND
 - iv. According to the prescriber, patient meets ONE of the following (a or b):
 - a) Female* patient: Alcohol consumption is < 20 grams/day; OR

Note: One standard drink (or one alcoholic drink equivalent) contains roughly 14 grams of pure alcohol, which is found in 12 ounces of regular beer, 5 ounces of wine, or 1.5 ounces of distilled spirits.

- b) Male* patient: Alcohol consumption < 30 grams/day; AND
Note: One standard drink (or one alcoholic drink equivalent) contains roughly 14 grams of pure alcohol, which is found in 12 ounces of regular beer, 5 ounces of wine, or 1.5 ounces of distilled spirits.
- v. The medication will be used in combination with appropriate diet and exercise therapy; AND
- vi. The medication is prescribed by or in consultation with an endocrinologist, gastroenterologist, or hepatologist.

*Refer to the Policy Statement

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Rezdiffra is not recommended in the following situations:

- 176. **Metabolic-Dysfunction Associated Steatotic Liver Disease (MASLD)/Non-Alcoholic Fatty Liver Disease (NAFLD).** Resmetirom is indicated in patients with non-cirrhotic NASH with moderate to advanced liver fibrosis.¹ NAFLD and NASH include the presence of steatosis; however, NASH additionally involves inflammation and injury to liver cells.²
- 177. **Metabolic-Dysfunction Associated Steatohepatitis (MASH)/Non-Alcoholic Steatohepatitis (NASH) with Cirrhosis.** Resmetirom is indicated in patients with non-cirrhotic NASH with moderate to advanced liver fibrosis.¹ The safety and effectiveness of Rezdiffra have not been established in patients with NASH cirrhosis. MEASTRO-NASH-OUTCOMES is an ongoing trial to assess the efficacy of Rezdiffra in adults with NASH with well-compensated cirrhosis (Child-Pugh A) [n = 700].⁸ Results are anticipated in 2025.
- 178. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hepatology – Bylvay Prior Authorization Policy

- Bylvay™ (odevixibat capsules and oral pellets – Albireo Pharma)

REVIEW DATE: 07/24/2024

OVERVIEW

Bylvay, an ileal bile acid transporter (IBAT) inhibitor, is indicated for the treatment of:

- Pruritus in patients ≥ 3 months of age with **progressive familial intrahepatic cholestasis (PFIC)**.¹
- Cholestatic pruritus in patients ≥ 12 months of age with **Alagille syndrome (ALGS)**.¹

Disease Overview

PFIC is a group of rare, autosomal recessive liver diseases defined by genetic mutations affecting bile acid transporters (e.g., mutation of the *ATP8B1* gene, *ABCB11* gene, *ABCB4* gene, *TJP2* gene, *NR1H4* gene, and *MYO5B* gene).²⁻⁴ **ALGS** is a rare liver disease defined by genetic deletion or mutation affecting bile acid transporters (e.g., deletion or mutation of the *JAG1* gene or *NOTCH2* gene).^{5,8,9} Progression of both diseases can cause liver fibrosis, cirrhosis, or end-stage liver disease and leads to death at an early age in life (infancy to adolescence).

Cholestasis, jaundice, and pruritus are common symptoms in patients with PFIC and ALGS.^{8,9} Although the complete mechanism by which Bylvay improves pruritus in these patients is unknown, it may involve inhibition of the IBAT, which results in decreased reuptake of bile salts, as observed by a decrease in serum bile acids. Cholestyramine, rifampicin, and ursodeoxycholic acid (ursodiol) have been used off-label for decades to alleviate symptoms related to PFIC and ALGS.^{5,6,9} Cholestyramine, ursodeoxycholic acid, rifampicin, naltrexone, and sertraline are recommended in clinical practice guidelines from the European Association for the Study of the Liver (2009).⁷

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Bylvay. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Bylvay as well as the monitoring required for adverse events and long-term efficacy, approval requires Bylvay to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Bylvay is recommended in those who meet the following criteria:

FDA-Approved Indication

60. Progressive Familial Intrahepatic Cholestasis. Approve for the duration noted if the patient meets ONE of the following (A or B):

- A) **Initial Therapy.** Approve for 6 months if the patient meets ALL of the following (i, ii, iii, iv, v, vi and vii):

07/24/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- i. Patient is ≥ 3 months of age; AND
- ii. Patient has moderate-to-severe pruritus, according to the prescriber; AND
- iii. Diagnosis of progressive familial intrahepatic cholestasis was confirmed by genetic testing demonstrating a gene mutation affiliated with progressive familial intrahepatic cholestasis; AND

Note: Gene mutations affiliated with progressive familial intrahepatic cholestasis include the *ATP8B1* gene, *ABCB11* gene, *ABCB4* gene, *TJP2* gene, *NR1H4* gene, and *MYO5B* gene.

- iv. Patient has a serum bile acid concentration above the upper limit of the normal reference range for the reporting laboratory; AND
- v. Patient has tried at least two systemic medications for progressive familial intrahepatic cholestasis, unless contraindicated; AND
- Note: Systemic medications for progressive familial intrahepatic cholestasis include cholestyramine, naltrexone, rifampicin, sertraline, and ursodeoxycholic acid (ursodiol).
- vi. Patient does not have any of the following (a, b, or c):
 - a) Cirrhosis; OR
 - b) Portal hypertension; OR
 - c) History of a hepatic decompensation event; AND

Note: Examples of a hepatic decompensation event include variceal hemorrhage, ascites, and hepatic encephalopathy.

- viii. The medication is prescribed by or in consultation with a hepatologist, gastroenterologist, or a physician who specializes in progressive familial intrahepatic cholestasis.

C) Patient is Currently Receiving Bylvay. Approve for 1 year if the patient meets ALL of the following (i, ii, and iii):

- iii. Patient does not have any of the following (a, b, or c):

- a) Cirrhosis; OR
- b) Portal hypertension; OR
- c) History of a hepatic decompensation event; AND

Note: Examples of a hepatic decompensation event include variceal hemorrhage, ascites, and hepatic encephalopathy.

- iv. Patient had response to therapy, as determined by the prescriber; AND
- Note: Examples of response to therapy include decrease in serum bile acids and decrease in pruritus.
- iv. The medication is prescribed by or in consultation with a hepatologist, gastroenterologist, or a physician who specializes in progressive familial intrahepatic cholestasis.

61. Alagille Syndrome. Approve for the duration noted if the patient meets ONE of the following (A or B):

A) Initial Therapy. Approve for 6 months if the patient meets ALL of the following (i, ii, iii, iv, v, vi and vii):

- i. Patient is ≥ 12 months of age; AND
- ii. Patient has moderate-to-severe pruritus, according to the prescriber; AND
- iii. Diagnosis of Alagille syndrome was confirmed by genetic testing demonstrating a *JAG1* or *NOTCH2* deletion or mutation; AND
- iv. Patient has a serum bile acid concentration above the upper limit of the normal reference range for the reporting laboratory; AND
- v. Patient has tried at least two systemic medications for Alagille syndrome, unless contraindicated; AND
- Note: Systemic medications for Alagille syndrome include cholestyramine, naltrexone, rifampicin, sertraline, and ursodeoxycholic acid (ursodiol).
- vi. Patient does not have any of the following (a, b, or c):

- a) Cirrhosis; OR
- b) Portal hypertension; OR
- c) History of a hepatic decompensation event; AND
Note: Examples of a hepatic decompensation event include variceal hemorrhage, ascites, and hepatic encephalopathy.
- vii. The medication is prescribed by or in consultation with a hepatologist, gastroenterologist, or a physician who specializes in Alagille syndrome.
- D) Patient is Currently Receiving Bylvay. Approve for 1 year if the patient meets ALL of the following (i, ii, and iii):
 - i. Patient does not have any of the following (a, b, or c):
 - a) Cirrhosis; OR
 - b) Portal hypertension; OR
 - c) of a hepatic decompensation event; AND
Note: Examples of a hepatic decompensation event include variceal hemorrhage, ascites, and hepatic encephalopathy.
 - ii. Patient had response to therapy, as determined by the prescriber; AND
Note: Examples of response to therapy include decrease in serum bile acids and decrease in pruritus.
 - iii. The medication is prescribed by or in consultation with a hepatologist, gastroenterologist, or a physician who specializes in Alagille syndrome.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Bylvay is not recommended in the following situations:

179. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

- POLICY:** Hereditary Angioedema – C1 Esterase Inhibitors (Intravenous) Prior Authorization Policy
- Berinert® (C1 esterase inhibitor [human] intravenous infusion – CSL Behring)
 - Cinryze® (C1 esterase inhibitor [human] intravenous infusion – Takeda)
 - Ruconest® (C1 esterase inhibitor [recombinant] intravenous infusion – Pharming)

REVIEW DATE: 10/09/2024

OVERVIEW

Berinert, Cinryze, and Ruconest are C1 esterase inhibitor (C1-INH) replacement therapies for hereditary angioedema (HAE).¹⁻³ Cinryze and Berinert are human plasma-derived C1-INH; Ruconest is a recombinant C1-INH purified from milk of transgenic rabbits. Labeled indications are as follows:

- Berinert is indicated for the **treatment of acute abdominal, facial, or laryngeal HAE attacks** in adults and pediatric patients.¹
- Cinryze is indicated for routine **prophylaxis against HAE attacks** in patients ≥ 6 years of age.²
- Ruconest is indicated for the **treatment of acute HAE attacks** in adults and adolescent patients.³

Of note, although Cinryze is labeled for use in the prophylactic setting and Berinert is labeled for use in the acute treatment setting, use of Cinryze in the acute setting and Berinert in the prophylactic setting has been reported in the literature.^{4,5}

Guidelines

Acute Treatment of HAE Attacks

According to US HAE Association Medical Advisory Board Guidelines (2020), when HAE is suspected based on clinical presentation, appropriate testing includes measurement of the serum C4 level, C1-INH antigenic level, and C1-INH functional level.⁶ Low C4 plus low C1-INH antigenic or functional level is consistent with a diagnosis of HAE types I/II. The goal of acute therapy is to minimize morbidity and prevent mortality from an ongoing HAE attack. Patients must have ready access to effective on-demand medication to administer at the onset of an HAE attack. All HAE attacks are eligible for treatment, irrespective of the location of swelling or severity of the attack. First-line treatments include plasma-derived C1-INH, Ruconest, Kalbitor® (ecallantide subcutaneous [SC] injection), and icatibant (Firazyr®, generic).

In guidelines from the World Allergy Organization (WAO)/European Academy of Allergy and Clinical Immunology (EAACI) [2021], it is recommended that all attacks be treated with either IV C1-INH, Kalbitor, or icatibant (evidence level A for all).⁷ Regarding IV C1-INH, it is noted that Berinert and Cinryze are both plasma-derived products available for this use, although indications vary globally. It is essential that patients have on-demand medication to treat all attacks; thus, the guidelines recommend that patients have and carry medication for treatment of at least two attacks.

Long-Term Prophylaxis

US HAE Association Medical Advisory Board Guidelines (2020) note the decision on when to use long-term prophylaxis cannot be made on rigid criteria but should reflect the needs of the individual patient.⁶ First-line medications for HAE I/II include intravenous (IV) C1-INH, Haegarda® (C1-INH [human] SC injection), or Takhzyro® (landelumab-flyo SC injection). The guideline was written prior to approval of Orladeyo® (berotralstat capsules).

10/09/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

According to WAO/EAACI guidelines (2021), it is recommended to evaluate for long-term prophylaxis at every visit, taking disease activity, burden, and control as well as patient preference into consideration.⁷ The following therapies are supported as first-line options for long-term prophylaxis: plasma-derived C1-INH (87% agreement), Takhzyro (89% agreement), and Orladeyo (81% agreement). With regard to plasma-derived C1-INH, it is noted that Haegarda provided very good and dose-dependent preventative effects on the occurrence of HAE attacks; the subcutaneous route may provide more convenient administration and maintain improved steady-state plasma concentrations compared with the IV route. Of note, androgens are not recommended in the first-line setting for long-term prophylaxis. Recommendations are not made regarding long-term prophylaxis in HAE with normal C1-INH.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Berinert, Cinryze, and Ruconest. Because of the specialized skills required for evaluation and diagnosis of patients treated with Berinert, Cinryze, or Ruconest, as well as monitoring required for adverse events and long-term efficacy, approval requires the medication to be prescribed by or in consultation with a physician who specializes in the condition being treated. All approvals are provided for the duration noted below. A patient who has previously met initial therapy criteria for Berinert, Cinryze, and Ruconest for the requested indication under the Coverage Review Department and is currently receiving the requested therapy is only required to meet the continuation therapy criteria (i.e., currently receiving Berinert, Cinryze, or Ruconest). If past criteria have not been met under the Coverage Review Department and the patient is currently receiving Berinert, Cinryze, or Ruconest, initial therapy criteria must be met.

Documentation: Documentation will be required where noted in the criteria as **[documentation required]**. Documentation may include, but is not limited to, chart notes, laboratory records, and prescription claims records.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

I. Coverage of Berinert or Cinryze is recommended in those who meet one of the following criteria:

FDA-Approved Indications

36. Hereditary Angioedema (HAE) Due to C1 Inhibitor (C1-INH) Deficiency – Prophylaxis. Approve Berinert or Cinryze for 1 year if the patient meets ONE of the following (A or B):

- Initial therapy. Approve if the patient meets BOTH of the following (i and ii):
 - Patient has HAE type I or type II as confirmed by the following diagnostic criteria (a and b):

Note: A diagnosis of HAE with normal C1-INH (also known as HAE type III) does NOT satisfy this requirement.

- Patient has low levels of functional C1-INH protein (< 50% of normal) at baseline, as defined by the laboratory reference values **[documentation required]**; AND
- Patient has lower than normal serum C4 levels at baseline, as defined by the laboratory reference values **[documentation required]**; AND

- The medication is prescribed by or in consultation with an allergist/immunologist or a physician who specializes in the treatment of HAE or related disorders.
- Patient is currently receiving Berinert or Cinryze prophylaxis. Approve if the patient meets ALL of the following (i, ii, and iii):

Note: If the patient is currently receiving the requested therapy, but has not previously received approval of Berinert or Cinryze for this indication through the Coverage Review Department, review under criteria for Initial Therapy.

- Patient has a diagnosis of HAE type I or type II **[documentation required]**; AND

Note: A diagnosis of HAE with normal C1-INH (also known as HAE type III) does NOT satisfy this requirement.

- According to the prescriber, the patient has had a favorable clinical response since initiating Berinert or Cinryze prophylactic therapy compared with baseline (i.e., prior to initiating prophylactic therapy); AND

Note: Examples of a favorable clinical response include decrease in HAE acute attack frequency, decrease in HAE attack severity, or decrease in duration of HAE attacks.

- The medication is prescribed by or in consultation with an allergist/immunologist or a physician who specializes in the treatment of HAE or related disorders.

37. Hereditary Angioedema (HAE) Due to C1 Inhibitor (C1-INH) Deficiency – Treatment of Acute Attacks. Approve Berinert or Cinryze for 1 year if the patient meets ONE of the following (A or B):

A) Initial therapy. Approve if the patient meets BOTH of the following (i and ii):

- i. Patient has HAE type I or type II as confirmed by following (a and b):

Note: A diagnosis of HAE with normal C1-INH (also known as HAE type III) does NOT satisfy this requirement.

- a) Patient has low levels of functional C1-INH protein (< 50% of normal) at baseline, as defined by the laboratory reference values **[documentation required]**; AND
- b) Patient has lower than normal serum C4 levels at baseline, as defined by the laboratory reference values **[documentation required]**; AND

- ii. The medication is prescribed by or in consultation with an allergist/immunologist or a physician who specializes in the treatment of HAE or related disorders.

B) Patient who has treated previous acute HAE attacks with Berinert or Cinryze. Approve if the patient meets ALL of the following (i, ii, and iii):

Note: If the patient is currently receiving the requested therapy, but has not previously received approval of Berinert or Cinryze for this indication through the Coverage Review Department, review under criteria for Initial Therapy.

- i. Patient has a diagnosis of HAE type I or type II **[documentation required]**; AND

Note: A diagnosis of HAE with normal C1-INH (also known as HAE type III) does NOT satisfy this requirement.

- ii. According to the prescriber, the patient has had a favorable clinical response with Berinert or Cinryze treatment; AND

Note: Examples of a favorable clinical response include decrease in the duration of HAE attacks, quick onset of symptom relief, complete resolution of symptoms, or decrease in HAE acute attack frequency or severity.

- iii. The medication is prescribed by or in consultation with an allergist/immunologist or a physician who specializes in the treatment of HAE or related disorders.

II. Coverage of Ruconest is recommended in those who meet the following criteria:

FDA-Approved Indication

1. **Hereditary Angioedema (HAE) Due to C1 Inhibitor (C1-INH) Deficiency – Treatment of Acute Attacks.** Approve Ruconest for 1 year if the patient meets ONE of the following (A or B):

A) Initial therapy. Approve if the patient meets BOTH of the following (i and ii):

i. Patient has HAE type I or type II as confirmed by the following (a and b):

Note: A diagnosis of HAE with normal C1-INH (also known as HAE type III) does NOT satisfy this requirement.

a) Patient has low levels of functional C1-INH protein (< 50% of normal) at baseline, as defined by the laboratory reference values **[documentation required]**; AND

b) Patient has lower than normal serum C4 levels at baseline, as defined by the laboratory reference values **[documentation required]**; AND

ii. The medication is prescribed by or in consultation with an allergist/immunologist or a physician who specializes in the treatment of HAE or related disorders.

B) Patient who has treated previous acute HAE attacks with Ruconest. Approve if the patient meets ALL of the following (i, ii, and iii):

Note: If the patient is currently receiving the requested therapy, but has not previously received approval of Ruconest for this indication through the Coverage Review Department, review under criteria for Initial Therapy.

i. Patient has a diagnosis of HAE type I or type II **[documentation required]**; AND

Note: A diagnosis of HAE with normal C1-INH (also known as HAE type III) does NOT satisfy this requirement.

ii. According to the prescriber, the patient has had a favorable clinical response with Ruconest treatment; AND

Note: Examples of a favorable clinical response include decrease in the duration of HAE attacks, quick onset of symptom relief, complete resolution of symptoms, or decrease in HAE acute attack frequency or severity.

iii. The medication is prescribed by or in consultation with an allergist/immunologist or a physician who specializes in the treatment of HAE or related disorders.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Berinert, Cinryze, or Ruconest is not recommended in the following situations:

38. **Hereditary Angioedema (HAE) Prophylaxis (Ruconest ONLY).** Ruconest is not FDA-approved for prophylaxis of HAE attacks. A small (n = 32) Phase II, randomized, double-blind, placebo-controlled trial in adults and adolescents ≥ 13 years of age showed efficacy of Ruconest over placebo for reducing mean monthly rate of HAE attacks ($P < 0.0001$).⁸ At this time, evidence is not sufficient to support Ruconest use for HAE prophylaxis.

Note: This Condition Not Recommended for Approval does not apply to Berinert or Cinryze.

39. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hereditary Angioedema – C1 Esterase Inhibitors (Subcutaneous) Prior Authorization Policy

- Haegarda® (C1 esterase inhibitor [human] subcutaneous injection – CSL Behring)

REVIEW DATE: 10/09/2024

OVERVIEW

Haegarda, a human plasma-derived C1 esterase inhibitor (C1-INH), is indicated for **routine prophylaxis to prevent hereditary angioedema (HAE) attacks** in adults and pediatric patients ≥ 6 years of age.¹

Guidelines

According to US HAE Association Medical Advisory Board Guidelines (2020), when HAE is suspected based on clinical presentation, appropriate testing includes measurement of the serum C4 level, C1-INH antigenic level, and C1-INH functional level.² Low C4 plus low C1-INH antigenic or functional level is consistent with a diagnosis of HAE types I/II. The decision on when to use long-term prophylaxis cannot be made on rigid criteria but should reflect the needs of the individual patient. First-line medications for HAE I/II include intravenous C1-INH, Haegarda, or Takhzyro® (lanadelumab-flyo subcutaneous injection). The guideline was written prior to approval of Orladeyo® (berotralstat capsules).

According to World Allergy Organization/European Academy of Allergy and Clinical Immunology guidelines (2021), it is recommended to evaluate for long-term prophylaxis at every visit, taking disease activity, burden, and control as well as patient preference into consideration.³ The following therapies are supported as first-line options for long-term prophylaxis: plasma-derived C1-INH (87% agreement), Takhzyro (89% agreement), and Orladeyo (81% agreement). With regard to plasma-derived C1-INH, it is noted that Haegarda provided very good and dose-dependent preventative effects on the occurrence of HAE attacks; the subcutaneous route may provide more convenient administration and maintain improved steady-state plasma concentrations compared with the intravenous route. Of note, androgens are not recommended in the first-line setting for long-term prophylaxis. Recommendations are not made regarding long-term prophylaxis in HAE with normal C1-INH.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Haegarda. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Haegarda as well as the monitoring for adverse events and long-term efficacy, approval requires Haegarda to be prescribed by or in consultation with a physician who specializes in the condition being treated. A patient who has previously met initial therapy criteria for Haegarda for the requested indication under the Coverage Review Department and is currently receiving the requested therapy is only required to meet the continuation therapy criteria (i.e., currently receiving Haegarda). If past criteria have not been met under the Coverage Review Department and the patient is currently receiving Haegarda, initial therapy criteria must be met.

Documentation: Documentation will be required where noted in the criteria as **[documentation required]**. Documentation may include, but is not limited to, chart notes, laboratory records, and prescription claims records.

Automation: None.

10/09/2024

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Haegarda is recommended in those who meet the following criteria:

FDA-Approved Indication

1. **Hereditary Angioedema (HAE) Due to C1 Inhibitor (C1-INH) Deficiency – Prophylaxis.** Approve Haegarda for 1 year if the patient meets ONE of the following (A or B):

- Initial therapy. Approve if the patient meets BOTH of the following (i and ii):

- Patient has HAE type I or type II as confirmed by the following diagnostic criteria (a and b):

Note: A diagnosis of HAE with normal C1-INH (also known as HAE type III) does NOT satisfy this requirement.

- Patient has low levels of functional C1-INH protein (< 50% of normal) **at baseline**, as defined by the laboratory reference values **[documentation required]**; AND
- Patient has lower than normal serum C4 levels **at baseline**, as defined by the laboratory reference values **[documentation required]**; AND

- The medication is prescribed by or in consultation with an allergist/immunologist or a physician who specializes in the treatment of HAE or related disorders.

- Patient is currently receiving Haegarda prophylaxis. Approve if the patient meets ALL of the following (i, ii, and iii):

Note: If the patient is currently receiving the requested therapy, but has not previously received approval of Haegarda for this indication through the Coverage Review Department, review under criteria for Initial Therapy.

- Patient has a diagnosis of HAE type I or type II **[documentation required]**; AND

Note: A diagnosis of HAE with normal C1-INH (also known as HAE type III) does NOT satisfy this requirement.

- According to the prescriber, the patient has had a favorable clinical response since initiating Haegarda prophylactic therapy compared with baseline (i.e., prior to initiating prophylactic therapy); AND

Note: Examples of a favorable clinical response include decrease in HAE acute attack frequency, decrease in HAE attack severity, or decrease in duration of HAE attacks.

- The medication is prescribed by or in consultation with an allergist/immunologist or a physician who specializes in the treatment of HAE or related disorders.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Haegarda is not recommended in the following situations:

40. **Concomitant Use with Other Hereditary Angioedema (HAE) Prophylactic Therapies.** Haegarda has not been studied in combination with other prophylactic therapies for HAE, and combination therapy for long-term prophylactic use is not recommended. Patients may use other medications,

including Cinryze® (C1 esterase inhibitor [human] intravenous infusion), for treatment of acute HAE attacks, and for short-term (procedural) prophylaxis.

Note: Examples of other HAE prophylactic therapies include Cinryze (C1 esterase inhibitor [human] intravenous infusion), Orladeyo (berotralstat capsules), and Takhzyro (lanadelumab-flyo subcutaneous injection).

41. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

- POLICY:** Hereditary Angioedema – Icatibant Prior Authorization Policy
- Firazyr[®] (icatibant subcutaneous injection – Takeda, generic)
 - Sajazir[™] (icatibant subcutaneous injection – Cycle)

REVIEW DATE: 10/09/2024

OVERVIEW

Icatibant is a synthetic decapeptide that is indicated for the **treatment of acute hereditary angioedema (HAE) attacks** in adults ≥ 18 years of age.¹

Guidelines

According to US HAE Association Medical Advisory Board Guidelines (2020), when HAE is suspected based on clinical presentation, appropriate testing includes measurement of the serum C4 level, C1 esterase inhibitor (C1-INH) antigenic level, and C1-INH functional level.² Low C4 plus low C1-INH antigenic or functional level is consistent with a diagnosis of HAE types I/II. The goal of acute therapy is to minimize morbidity and prevent mortality from an ongoing HAE attack. Patients must have ready access to effective on-demand medication to administer at the onset of an HAE attack. All HAE attacks are eligible for treatment, irrespective of the location of swelling or severity of the attack. First-line treatments include plasma-derived C1-INH, Ruconest[®] (C1-INH [recombinant] intravenous [IV] infusion), Kalbitor[®] (ecallantide subcutaneous injection), and icatibant.

In guidelines from the World Allergy Organization/European Academy of Allergy and Clinical Immunology (2021), it is recommended that all attacks be treated with either IV C1-INH, Kalbitor, or icatibant (evidence level A for all).³ Regarding IV C1-INH, it is noted that Berinert[®] (C1 esterase inhibitor [human] IV infusion) and Cinryze[®] (C1 esterase inhibitor [human] IV infusion) are both plasma-derived products available for this use, although indications vary globally. It is essential that patients have on-demand medication to treat all attacks; thus, the guidelines recommend that patients have and carry medication for treatment of at least two attacks.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of icatibant. Because of the specialized skills required for evaluation and diagnosis of patients treated with icatibant, approval requires icatibant to be prescribed by or in consultation with a physician who specializes in the condition being treated. All approvals are provided for the duration noted below. A patient who has previously met initial therapy criteria for icatibant for the requested indication under the Coverage Review Department and is currently receiving the requested therapy is only required to meet the continuation therapy criteria (i.e., patient who has treated previous HAE attacks with icatibant). If past criteria have not been met under the Coverage Review Department and the patient has treated previous HAE attacks with icatibant, initial therapy criteria must be met.

Documentation: Documentation will be required where noted in the criteria as **[documentation required]**. Documentation may include, but is not limited to, chart notes, laboratory records, and prescription claims records.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of icatibant is recommended in those who meet the following criteria:

FDA-Approved Indication

1. Hereditary Angioedema (HAE) Due to C1 Inhibitor (C1-INH) Deficiency – Treatment of Acute Attacks. Approve for 1 year if the patient meets ONE of the following (A or B):

i. Initial therapy. Approve if the patient meets BOTH of the following (i and ii):

- a) Patient has HAE type I or type II as confirmed by the following diagnostic criteria (a and b):

Note: A diagnosis of HAE with normal C1-INH (also known as HAE type III) does NOT satisfy this requirement.

1. Patient has low levels of functional C1-INH protein (< 50% of normal) **at baseline**, as defined by the laboratory reference values **[documentation required]**; AND

2. Patient has lower than normal serum C4 levels **at baseline**, as defined by the laboratory reference values **[documentation required]**; AND

- b) The medication is prescribed by or in consultation with an allergist/immunologist or a physician who specializes in the treatment of HAE or related disorders.

ii. Patient who has treated previous HAE attacks with icatibant. Approve if the patient meets ALL of the following (i, ii, and iii):

Note: If the patient is currently receiving the requested therapy but has not previously received approval of icatibant for this indication through the Coverage Review Department, review under criteria for Initial Therapy.

- a) Patient has a diagnosis of HAE type I or type II **[documentation required]**; AND

Note: A diagnosis of HAE with normal C1-INH (also known as HAE type III) does NOT satisfy this requirement.

- b) According to the prescriber, the patient has had a favorable clinical response with icatibant treatment; AND

Note: Examples of a favorable clinical response include decrease in the duration of HAE attacks, quick onset of symptom relief, complete resolution of symptoms, or decrease in HAE acute attack frequency or severity.

- c) The medication is prescribed by or in consultation with an allergist/immunologist or a physician who specializes in the treatment of HAE or related disorders.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of icatibant is not recommended in the following circumstances:

42. Hereditary Angioedema (HAE) Prophylaxis. Data are not available and icatibant is not indicated for prophylaxis of HAE attacks.

43. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hereditary Angioedema – Kalbitor Prior Authorization Policy

- Kalbitor® (ecallantide subcutaneous injection – Takeda)

REVIEW DATE: 10/09/2024

OVERVIEW

Kalbitor, a plasma kallikrein inhibitor, is indicated for the **treatment of acute attacks of hereditary angioedema (HAE)** in patients ≥ 12 years of age.¹

Potentially serious hypersensitivity reactions, including anaphylaxis, have occurred in patients treated with Kalbitor.¹ Kalbitor should only be administered by a healthcare professional with appropriate medical support to manage anaphylaxis and HAE.

Guidelines

According to US HAE Association Medical Advisory Board Guidelines (2020), when HAE is suspected based on clinical presentation, appropriate testing includes measurement of the serum C4 level, C1 esterase inhibitor (C1-INH) antigenic level, and C1-INH functional level.² Low C4 plus low C1-INH antigenic or functional level is consistent with a diagnosis of HAE types I/II. The goal of acute therapy is to minimize morbidity and prevent mortality from an ongoing HAE attack. Patients must have ready access to effective on-demand medication to administer at the onset of an HAE attack. All HAE attacks are eligible for treatment, irrespective of the location of swelling or severity of the attack. First-line treatments include plasma-derived C1-INH, Ruconest® (C1-INH [recombinant] intravenous [IV] infusion), Kalbitor, and icatibant.

In guidelines from the World Allergy Organization/European Academy of Allergy and Clinical Immunology (2021), it is recommended that all attacks be treated with either IV C1-INH, Kalbitor, or icatibant (evidence level A for all).³ Regarding IV C1-INH, it is noted that Berinert® (C1 esterase inhibitor [human] IV infusion) and Cinryze® (C1 esterase inhibitor [human] IV infusion) are both plasma-derived products available for this use, although indications vary globally. It is essential that patients have on-demand medication to treat all attacks; thus, the guidelines recommend that patients have and carry medication for treatment of at least two attacks.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Kalbitor. Because of the specialized skills required for the evaluation and diagnosis of patients treated with Kalbitor, approval requires Kalbitor to be prescribed by or in consultation with a physician who specializes in the condition being treated. All approvals are provided for the duration noted below. A patient who has previously met initial therapy criteria for Kalbitor for the requested indication under the Coverage Review Department and is currently receiving the requested therapy, is only required to meet the continuation criteria (i.e., patient who has treated previous acute HAE attacks with Kalbitor). If past criteria have not been met under the Coverage Review Department and the patient has treated previous HAE attacks with Kalbitor, initial therapy criteria must be met.

Documentation: Documentation will be required where noted in the criteria as **[documentation required]**. Documentation may include, but is not limited to, chart notes, laboratory records, and prescription claims records.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Kalbitor is recommended in those who meet the following criteria:

FDA-Approved Indication

2. Hereditary Angioedema (HAE) Due to C1 Inhibitor (C1-INH) Deficiency – Treatment of Acute Attacks. Approve Kalbitor for 1 year if the patient meets ONE of the following (A or B):

iii. Initial therapy. Approve if the patient meets BOTH of the following (i and ii):

- a) Patient has HAE type I or type II as confirmed by the following diagnostic criteria (a and b):

Note: A diagnosis of HAE with normal C1-INH (also known as HAE type III) does NOT satisfy this requirement.

1. Patient has low levels of functional C1-INH protein (< 50% of normal) at baseline, as defined by the laboratory reference values **[documentation required]**; AND
2. Patient has lower than normal serum C4 levels at baseline, as defined by the laboratory reference values **[documentation required]**; AND

- b) The medication is prescribed by or in consultation with an allergist/immunologist or a physician that specializes in the treatment of HAE or related disorders.

iv. Patient who has treated previous acute HAE attacks with Kalbitor. Approve if the patient meets ALL of the following (i, ii, and iii):

Note: If the patient is currently receiving the requested therapy but has not previously received approval of Kalbitor for this indication through the Coverage Review Department, review under criteria for Initial Therapy.

- a) Patient has a diagnosis of HAE type I or type II **[documentation required]**; AND

Note: A diagnosis of HAE with normal C1-INH (also known as HAE type III) does NOT satisfy this requirement.

- b) According to the prescriber, the patient has had a favorable clinical response with Kalbitor treatment; AND

Note: Examples of a favorable clinical response include decrease in the duration of HAE attacks, quick onset of symptom relief, complete resolution of symptoms, or decrease in HAE acute attack frequency or severity.

- c) The medication is prescribed by or in consultation with an allergist/immunologist or a physician that specializes in the treatment of HAE or related disorders.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Kalbitor is not recommended in the following situations:

5. Hereditary Angioedema (HAE) Prophylaxis. Data are not available and Kalbitor is not indicated for the prophylaxis of HAE attacks.

6. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hereditary Angioedema – Orladeyo Prior Authorization Policy

- Orladeyo® (berotralstat capsules – Biocryst)

REVIEW DATE: 10/09/2024

OVERVIEW

Orladeyo, an inhibitor of plasma kallikrein, is indicated for **prophylaxis to prevent attacks of hereditary angioedema (HAE)** in patients ≥ 12 years of age.¹

Guidelines

According to US HAE Association Medical Advisory Board Guidelines (2020), when HAE is suspected based on clinical presentation, appropriate testing includes measurement of the serum C4 level, C1 esterase inhibitor (C1-INH) antigenic level, and C1-INH functional level.² Low C4 plus low C1-INH antigenic or functional level is consistent with a diagnosis of HAE types I/II. The decision on when to use long-term prophylaxis cannot be made on rigid criteria but should reflect the needs of the individual patient. First-line medications for HAE I/II include intravenous C1-INH, Haegarda® (C1-INH [human] subcutaneous injection), or Takhzyro® (lanadelumab-flyo subcutaneous injection). The guideline was written prior to approval of Orladeyo.

According to World Allergy Organization/European Academy of Allergy and Clinical Immunology guidelines (2021), it is recommended to evaluate for long-term prophylaxis at every visit, taking disease activity, burden, and control as well as patient preference into consideration.³ The following therapies are supported as first-line options for long-term prophylaxis: plasma-derived C1-INH (87% agreement), Takhzyro (89% agreement), and Orladeyo (81% agreement). With regard to plasma-derived C1-INH, it is noted that Haegarda provided very good and dose-dependent preventative effects on the occurrence of HAE attacks; the subcutaneous route may provide more convenient administration and maintains improved steady-state plasma concentrations compared with the intravenous route. Of note, androgens are not recommended in the first-line setting for long-term prophylaxis. Recommendations are not made regarding long-term prophylaxis in HAE with normal C1-INH levels.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Orladeyo. Because of the specialized skills required for evaluation and diagnosis of patients treated with Orladeyo, approval requires Orladeyo to be prescribed by or in consultation with a physician who specializes in the condition being treated. A patient who has previously met initial therapy criteria for Orladeyo for the requested indication under the Coverage Review Department and is currently receiving the requested therapy is only required to meet the continuation therapy criteria (i.e., currently receiving Orladeyo). If past criteria have not been met under the Coverage Review Department and the patient is currently receiving Orladeyo, initial therapy criteria must be met. All approvals are provided for the duration noted below.

Documentation: Documentation will be required where noted in the criteria as **[documentation required]**. Documentation may include, but is not limited to, chart notes, laboratory records, and prescription claims records.

Automation: None.

10/09/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Orladeyo is recommended in those who meet the following criteria:

FDA-Approved Indication

1. **Hereditary Angioedema (HAE) Due to C1 Inhibitor (C1-INH) Deficiency – Prophylaxis.** Approve for 1 year if the patient meets ONE of the following (A or B):

- Initial therapy. Approve if the patient meets ALL of the following (i, ii, and iii):
 - Patient is ≥ 12 years of age; AND
 - Patient has HAE type I or type II as confirmed by the following diagnostic criteria (a and b):

Note: A diagnosis of HAE with normal C1-INH (also referred to as HAE type III) does NOT satisfy this requirement.

- Patient has low levels of functional C1-INH protein ($< 50\%$ of normal) at baseline, as defined by the laboratory reference values **[documentation required]**; AND
 - Patient has lower than normal serum C4 levels at baseline, as defined by the laboratory reference values **[documentation required]**; AND
 - The medication is prescribed by or in consultation with an allergist/immunologist or a physician who specializes in the treatment of HAE or related disorders.
- Patient is currently receiving Orladeyo. Approve if the patient meets ALL of the following (i, ii, iii, and iv):

Note: If the patient is currently receiving the requested therapy, but has not previously received approval of Orladeyo for this indication through the Coverage Review Department, review under criteria for Initial Therapy.

- Patient is ≥ 12 years of age; AND
- Patient has a diagnosis of HAE type I or type II **[documentation required]**; AND

Note: A diagnosis of HAE with normal C1-INH (also referred to as HAE type III) does NOT satisfy this requirement.

- According to the prescriber, the patient has had a favorable clinical response since initiating Orladeyo prophylactic therapy compared with baseline (i.e., prior to initiating prophylactic therapy); AND

Note: Examples of favorable clinical response include decrease in HAE acute attack frequency, decrease in HAE attack severity, or decrease in duration of HAE attacks.

- The medication is prescribed by or in consultation with an allergist/immunologist or a physician who specializes in the treatment of HAE or related disorders.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Orladeyo is not recommended in the following situations:

44. **Concomitant Use with Other Hereditary Angioedema (HAE) Prophylactic Therapies.** Note: Examples of other HAE prophylactic therapies include Cinryze (C1 esterase inhibitor [human])

10/09/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

intravenous infusion), Haegarda (C1 esterase inhibitor [human] subcutaneous injection), and Takhzyro (lanadelumab-flyo subcutaneous injection).

Orladeyo has not been studied in combination with other prophylactic therapies for HAE, and combination therapy for long-term prophylactic use is not recommended. Patients may use other medications, including Cinryze, for on-demand treatment of acute HAE attacks, and for short-term (procedural) prophylaxis.

45. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hereditary Angioedema – Takhzyro Prior Authorization Policy

- Takhzyro® (lanadelumab-flyo subcutaneous injection – Shire/Takeda)

REVIEW DATE: 10/09/2024

OVERVIEW

Takhzyro, a human monoclonal antibody inhibitor of plasma kallikrein, is indicated for **prophylaxis to prevent attacks of hereditary angioedema (HAE)** in patients ≥ 2 years of age.¹

Guidelines

According to US HAE Association Medical Advisory Board Guidelines (2020), when HAE is suspected based on clinical presentation, appropriate testing includes measurement of the serum C4 level, C1 esterase inhibitor (C1-INH) antigenic level, and C1-INH functional level.² Low C4 plus low C1-INH antigenic or functional level is consistent with a diagnosis of HAE types I/II. The decision on when to use long-term prophylaxis cannot be made on rigid criteria but should reflect the needs of the individual patient. First-line medications for HAE I/II include intravenous C1-INH, Haegarda® (C1-INH [human] subcutaneous injection), or Takhzyro. The guideline was written prior to approval of Orladeyo® (berotralstat capsules).

According to World Allergy Organization/European Academy of Allergy and Clinical Immunology guidelines (2021), it is recommended to evaluate for long-term prophylaxis at every visit, taking disease activity, burden, and control as well as patient preference into consideration.³ The following therapies are supported as first-line options for long-term prophylaxis: plasma-derived C1-INH (87% agreement), Takhzyro (89% agreement), and Orladeyo (81% agreement). With regard to plasma-derived C1-INH, it is noted that Haegarda provided very good and dose-dependent preventative effects on the occurrence of HAE attacks; the subcutaneous route may provide more convenient administration and maintain improved steady-state plasma concentrations compared with the intravenous route. Of note, androgens are not recommended in the first-line setting for long-term prophylaxis. Recommendations are not made regarding long-term prophylaxis in HAE with normal C1-INH.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Takhzyro. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Takhzyro as well as the monitoring required for adverse events and long-term efficacy, approval requires Takhzyro to be prescribed by or in consultation with a physician who specializes in the condition being treated. A patient who has previously met initial therapy criteria for Takhzyro for the requested indication under the Coverage Review Department and is currently receiving the requested therapy is only required to meet the continuation therapy criteria (i.e., currently receiving Takhzyro). If past criteria have not been met under the Coverage Review Department and the patient is currently receiving Takhzyro, initial therapy criteria must be met.

Documentation: Documentation will be required where noted in the criteria as **[documentation required]**. Documentation may include, but is not limited to, chart notes, laboratory records, and prescription claims records.

Automation: None.

10/09/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Takhzyro is recommended in those who meet the following criteria:

FDA-Approved Indication

1. **Hereditary Angioedema (HAE) Due to C1 Inhibitor (C1-INH) Deficiency – Prophylaxis.** Approve Takhzyro for 1 year if the patient meets ONE of the following (A or B):

- Initial therapy. Approve if the patient meets BOTH of the following (i and ii):

- Patient has HAE type I or type II as confirmed by the following diagnostic criteria (a and b):

Note: A diagnosis of HAE with normal C1-INH (also known as HAE type III) does NOT satisfy this requirement.

- Patient has low levels of functional C1-INH protein (< 50% of normal) at baseline, as defined by the laboratory reference values **[documentation required]**; AND
- Patient has lower than normal serum C4 levels at baseline, as defined by the laboratory reference values **[documentation required]**; AND

- The medication is prescribed by or in consultation with an allergist/immunologist or a physician who specializes in the treatment of HAE or related disorders.

- Patient is currently receiving Takhzyro prophylaxis. Approve if the patient meets ALL of the following (i, ii, and iii):

Note: If the patient is currently receiving the requested therapy, but has not previously received approval of Takhzyro for this indication through the Coverage Review Department, review under criteria for Initial Therapy.

- Patient has a diagnosis of HAE type I or type II **[documentation required]**; AND

Note: A diagnosis of HAE with normal C1-INH (also known as HAE type III) does NOT satisfy this requirement.

- According to the prescriber, the patient has had a favorable clinical response since initiating Takhzyro prophylactic therapy compared with baseline (i.e., prior to initiating prophylactic therapy); AND

Note: Examples of a favorable clinical response include decrease in HAE acute attack frequency, decrease in HAE attack severity, or decrease in duration of HAE attacks.

- The medication is prescribed by or in consultation with an allergist/immunologist or a physician who specializes in the treatment of HAE or related disorders.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Takhzyro is not recommended in the following situations:

46. **Concomitant Use with Other Hereditary Angioedema (HAE) Prophylactic Therapies.** Takhzyro has not been studied in combination with other prophylactic therapies for HAE, and combination therapy for long-term prophylactic use is not recommended. Patients may use other medications,

including Cinryze® (C1 esterase inhibitor [human] intravenous infusion), for on-demand treatment of acute HAE attacks, and for short-term (procedural) prophylaxis.

Note: Examples of other HAE prophylactic therapies include Cinryze (C1 esterase inhibitor [human] intravenous infusion), Haegarda (C1 esterase inhibitor [human] subcutaneous injection), and Orladeyo (berotralstat capsules).

47. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Homozygous Familial Hypercholesterolemia – Evkeeza Prior Authorization Policy

- Evkeeza® (evinacumab-dgnb intravenous infusion – Regeneron)

REVIEW DATE: 05/08/2024

OVERVIEW

Evkeeza, an angiopoietin-like 3 inhibitor, is indicated as an adjunct to other low-density lipoprotein cholesterol (LDL-C) lowering therapies for the treatment of **homozygous familial hypercholesterolemia** (HoFH) in patients ≥ 5 years of age.¹

In the pivotal trial that led to approval of Evkeeza, patients were receiving additional medications to lower LDL-C levels such as statins (94% [77% of patients at high-intensity statin doses]), a proprotein convertase subtilisin kexin type 9 (PCSK9) inhibitor (77%), ezetimibe (75%), and Juxtapid® (lomitapide capsules). Although some Phase II data are available,³ the safety and effectiveness of Evkeeza have not been established in patients with other causes of hypercholesterolemia, including those with heterozygous familial hypercholesterolemia (HeFH).¹ The effects of Evkeeza on cardiovascular (CV) morbidity and mortality have not been determined.

Disease Overview

Familial hypercholesterolemias, which include HeFH and HoFH, encompass a group of genetic defects that cause severe elevations in LDL-C levels, as well as other lipid parameters.^{4,5} HoFH impacts approximately 1 in 300,000 to 1,000,000 persons. The condition is most commonly due to impaired functionality of the low-density lipoprotein (LDL) receptor which leads to a low or absence of clearance of LDL-C from the circulation. Currently known causes of familial hypercholesterolemia include mutations in the LDL receptor, apolipoprotein B, or PCSK9 genes. Patients with familial hypercholesterolemia may have physical findings such as tendon or cutaneous xanthomas, which may occur in childhood. Individuals with familial hypercholesterolemia are at very high risk of atherosclerotic cardiovascular disease (ASCVD) at a premature age. Most guidelines recommended LDL-C targets of < 100 mg/dL for adults and < 70 mg/dL for adults with ASCVD or other risk factors. Statins are the initial treatment for familial hypercholesterolemia. For patients with HoFH, high-intensity statin therapy is recommended, with ezetimibe added as well. Therapy with a PCSK9 inhibitor (e.g., Repatha® [evolocumab subcutaneous injection], Praluent® [alirocumab subcutaneous injection]) is usually the next step. Juxtapid can be added onto maximal lipid-lowering therapy and Evkeeza may be considered. Combination therapy is required for most patients. LDL apheresis is recommended in certain circumstances. The diagnosis of HoFH can be done by genetic or clinical criteria.⁵ An untreated LDL-C (> 400 mg/dL) is suggestive of HoFH. Patients may have cutaneous or tendon xanthomas before 10 years of age and/or untreated elevated LDL-C levels consistent with HeFH in both parents. In the digenic form, one parent may have normal LDL-C levels and the other may have LDL-C levels consistent with HoFH.

Guidelines

Guidelines provide strategies for managing familial hypercholesterolemia, including HoFH, and mention the role of Evkeeza.^{5,6}

- **American College of Cardiology (2022):** Specialized therapies, one of which includes Evkeeza, may be needed to control LDL-C in certain patients (e.g., those with HoFH) who have had an inadequate response to statins, with or without ezetimibe, and PCSK9 inhibitors.⁶

05/08/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- **European Atherosclerosis Society (2023):** Clinical guidance by this organization recommends lipid-lowering therapy be initiated with high-intensity statin therapy and ezetimibe.⁵ A PCSK9 inhibitor can be added as well. If not at LDL-C goals, other agents can be alternatives as well (e.g., Juxtapid, Evkeeza). Lipoprotein apheresis may also be considered. The goal is to reduce LDL-C to < 115 mg/dL in children and adolescents, < 70 mg/dL in adults if no major ASCVD risk factors are present, and < 55 mg/dL if patients have ASCVD or major ASCVD risk factors.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Evkeeza. All approvals are provided for the duration noted below. A patient who has previously met Initial Therapy criteria for Evkeeza for the requested indication under the Coverage Review Department and is currently receiving Evkeeza is only required to meet continuation of therapy criteria (i.e., currently receiving therapy). If past criteria has not been met under the Coverage Review Department and the patient is currently receiving Evkeeza, or is restarting Evkeeza, Initial Therapy criteria must be met.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Evkeeza is recommended in those who meet the following criteria:

FDA-Approved Indication

62. Homozygous Familial Hypercholesterolemia. Approve for 1 year if the patient meets ONE of the following (A or B):

1. **Initial Therapy.** Approve if the patient meets ALL of the following (i, ii, iii, and iv):

i. Patient is ≥ 5 years of age; AND

ii. Patient meets ONE of the following (a, b, or c):

a) Patient has phenotypic confirmation of homozygous familial hypercholesterolemia; OR

Note: Examples include pathogenic variants at the low-density lipoprotein receptor (LDLR), apolipoprotein B (apo B), proprotein convertase subtilisin kexin type 9 (PCSK9), or low-density lipoprotein receptor adaptor protein 1 (LDLRAP1) gene.

b) Patient has an untreated low-density lipoprotein cholesterol (LDL-C) level > 400 mg/dL AND meets ONE of the following [(1) or (2)]:

Note: Untreated refers to prior to therapy with any antihyperlipidemic agent.

(1) Patient had clinical manifestations of homozygous familial hypercholesterolemia before the age of 10 years; OR

Note: Clinical manifestations of homozygous familial hypercholesterolemia are cutaneous xanthomas, tendon xanthomas, arcus cornea, tuberous xanthomas, or xanthelasma.

(2) At least one parent of the patient had untreated LDL-C levels or total cholesterol levels consistent with familial hypercholesterolemia; OR

Note: An example of familial hypercholesterolemia is an untreated LDL-C level ≥ 190 mg/dL and/or an untreated total cholesterol level > 250 mg/dL.

c) Patient has a treated LDL-C level ≥ 300 mg/dL AND meets ONE of the following [(1) or (2)]:

Note: Treated refers to after therapy with at least one antihyperlipidemic agent. Some examples of antihyperlipidemic agents include statins (e.g., atorvastatin, rosuvastatin, lovastatin, simvastatin, pravastatin), ezetimibe, a PCSK9 inhibitor (i.e., Repatha

[evolocumab subcutaneous injection, Praluent [alirocumab subcutaneous injection]], or Juxtapid (lomitapide capsules).

- (1) Patient had clinical manifestations of homozygous familial hypercholesterolemia before the age of 10 years; OR

Note: Examples of clinical manifestations of homozygous familial hypercholesterolemia are cutaneous xanthomas, tendon xanthomas, arcus cornea, tuberous xanthomas, or xanthelasma.

- (2) At least one parent of the patient had untreated LDL-C levels or total cholesterol levels consistent with familial hypercholesterolemia; AND

Note: An example of familial hypercholesterolemia is an untreated LDL-C ≥ 190 mg/dL and/or an untreated total cholesterol > 250 mg/dL.

iii. Patient meets ONE of the following (a or b):

- a) Patient meets ALL of the following [(1), (2), and (3)]:

- (1) Patient has tried one high-intensity statin therapy (i.e., atorvastatin ≥ 40 mg daily; rosuvastatin ≥ 20 mg daily [as a single entity or as a combination product]); AND

- (2) Patient has tried one high-intensity statin along with ezetimibe (as a single-entity or as a combination product) for ≥ 8 continuous weeks; AND

- (3) Low-density lipoprotein cholesterol level after this treatment regimen remains ≥ 70 mg/dL; OR

- b) Patient has been determined to be statin intolerant by meeting ONE of the following [(1) or (2)]:

- (1) Patient experienced statin-related rhabdomyolysis; OR

Note: Rhabdomyolysis is statin-induced muscle breakdown that is associated with markedly elevated creatine kinase levels (at least 10 times the upper limit of normal), along with evidence of end organ damage which can include signs of acute renal injury (noted by substantial increases in serum creatinine [Scr] levels [$a \geq 0.5$ mg/dL increase in Scr or doubling of the Scr] and/or myoglobinuria [myoglobin present in urine]).

- (2) Patient meets ALL of the following [(a), (b), and (c)]:

- (a) Patient experienced skeletal-related muscle symptoms; AND

Note: Examples of skeletal-related muscle symptoms include myopathy (muscle weakness) or myalgia (muscle aches, soreness, stiffness, or tenderness).

- (b) The skeletal-muscle related symptoms occurred while receiving separate trials of both atorvastatin and rosuvastatin (as single-entity or combination products); AND

- (c) When receiving separate trials of both atorvastatin and rosuvastatin (as single-entity or as combination products) the skeletal-related muscle symptoms resolved upon discontinuation of each respective statin therapy (atorvastatin and rosuvastatin); AND

Note: Examples of skeletal-related muscle symptoms include myopathy and myalgia.

iv. Patient meets ONE of the following (a, b, or c):

- a) Patient meets BOTH of the following [(1) and (2)]:

- (1) Patient has tried one PCSK9 inhibitor for ≥ 8 continuous weeks; AND

Note: Examples of PCSK9 inhibitors include Repatha (evolocumab subcutaneous injection) and Praluent (alirocumab subcutaneous injection).

- (2) The LDL-C level after this PCSK9 inhibitor therapy remains ≥ 70 mg/dL; OR

- b) Patient is known to have two LDL-receptor negative alleles; OR

- c) Patient is 5 to 9 years of age; OR

2. Patient Currently Receiving Evkeeza. Approve if according to the prescriber, the patient has experienced a response to therapy.

Note: Examples of a response to therapy include decreasing LDL-C, total cholesterol, non-high-density lipoprotein (non-HDL-C), or apolipoprotein B levels. Also, if the patient is currently receiving the requested therapy but has not previously received approval of Evkeeza for this specific indication through the Coverage Review Department, review under criteria for Initial Therapy. If the patient is restarting therapy with Evkeeza, Initial Therapy criteria must be met.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Evkeeza is not recommended in the following situations:

- 48. Heterozygous Familial Hypercholesterolemia.** The safety and effectiveness of Evkeeza have not been established in patients with hypercholesterolemia who do not have HoFH, including those with HeFH.¹
- 49. Hyperlipidemia.** Although data are available, the prescribing information for Evkeeza states that the safety and efficacy of Evkeeza have not been established in patients with other forms of hypercholesterolemia.^{1,3}
Note: This is not associated with HoFH and is referred to as combined hyperlipidemia, hypercholesterolemia (pure, primary), dyslipidemia, or increased/elevated LDL-C levels.
- 50.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Homozygous Familial Hypercholesterolemia – Juxtapid Prior Authorization Policy

- Juxtapid® (lomitapide capsules – Amryt)

REVIEW DATE: 05/08/2024

OVERVIEW

Juxtapid, a microsomal triglyceride transfer protein inhibitor, is indicated as an adjunct to a low fat diet and other lipid-lowering treatments, including low-density lipoprotein (LDL) apheresis where available, to reduce low-density lipoprotein cholesterol (LDL-C), total cholesterol, apolipoprotein B, and non-high-density lipoprotein cholesterol (non-HDL-C) in adults with **homozygous familial hypercholesterolemia** (HoFH).¹ Limitations of use include that the safety and efficacy of Juxtapid have not been established in patients with hypercholesterolemia who do not have HoFH, including those with heterozygous familial hypercholesterolemia (HeFH). Also, the effect of Juxtapid on cardiovascular (CV) morbidity and mortality have not been determined.

Repatha® (evolocumab subcutaneous injection) and Praluent® (alirocumab subcutaneous injection), two proprotein convertase subtilisin kexin type 9 (PCSK9) inhibitors, are indicated as an adjunct to diet and other LDL-lowering therapies (e.g., statins, ezetimibe, LDL apheresis) in patients with HoFH who require additional LDL-C lowering.^{2,3} It is notable that patients known to have two LDL-receptor negative alleles (little or no residual function) did not respond or had minimal response to these agents. PCSK9 inhibitors are well tolerated and are not associated with hepatotoxicity.² Simvastatin, atorvastatin, and rosuvastatin are statins that are indicated for the management of patients with HoFH.⁴⁻⁶ Ezetimibe is also indicated for use in combination with atorvastatin or simvastatin in patients with HoFH.⁷ Ezetimibe/simvastatin tablets are indicated for use in HoFH.⁸ Evkeeza® (evinacumab-dgnb intravenous infusion), an angiopoietin-like 3 inhibitor, is also indicated as an adjunct to other LDL-C lowering therapies for the treatment of HoFH in patients ≥ 5 years of age.⁹

Disease Overview

Familial hypercholesterolemias, which includes HeFH and HoFH, encompasses a group of genetic defects that causes severe elevations in LDL-C levels, as well as other lipid parameters.^{10,11} HoFH impacts approximately 1 in 300,000 to 1,000,000 persons. The condition is most commonly due to impaired functionality of the LDL receptor which leads to a low or absence of clearance of LDL-C from the circulation. Currently known causes of familial hypercholesterolemia include mutations in the LDL receptor, apolipoprotein B, or PCSK9 genes. Patients with familial hypercholesterolemia may have physical findings such as tendon or cutaneous xanthomas, which may occur in childhood. Individuals with familial hypercholesterolemia are at very high risk of atherosclerotic cardiovascular disease (ASCVD) at a premature age. Most guidelines recommended LDL-C targets of < 100 mg/dL for adults and < 70 mg/dL for adults with ASCVD or other risk factors. Statins are the initial treatment for familial hypercholesterolemia. For patients with HoFH, high-intensity statin therapy is recommended, with ezetimibe added as well. Therapy with a PCSK9 inhibitor (e.g., Repatha, Praluent) is usually the next step. Juxtapid can be added onto maximal lipid-lowering therapy and Evkeeza® (evinacumab-dgnb intravenous infusion) may be considered. Combination therapy is required for most patients. LDL apheresis is recommended in certain circumstances. The diagnosis of HoFH can be done by genetic or clinical criteria.¹⁰ An untreated LDL-C > 400 mg/dL is suggestive of HoFH. Patients may have cutaneous or tendon xanthomas before 10 years of age and/or untreated elevated LDL-C levels consistent with HeFH in both

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

parents. In the digenic form, one parent may have normal LDL-C levels and the other may have LDL-C levels consistent with HoFH.

Guidelines

- **American College of Cardiology Expert Consensus Decision Pathway on the Role of Non-statin Therapies (2022):** Specialized therapies, one of which includes Juxtapid, may be needed to control LDL-C in certain patients (e.g., those with HoFH) who have had an inadequate response to statins, with or without ezetimibe, and PCSK9 inhibitors.¹²
- **European Atherosclerosis Society (2023):** Clinical guidance by this organization recommends lipid-lowering therapy be initiated with high-intensity statin therapy and ezetimibe.¹¹ A PCSK9 inhibitor can be added as well. If patients are not at LDL-C goals, other agents can be alternatives as well (e.g., Juxtapid, Evkeeza). Lipoprotein apheresis may also be considered. The goal is to reduce LDL-C to < 115 mg/dL in children and adolescents, < 70 mg/dL in adults if no major ASCVD risk factors are present, and < 55 mg/dL if patients have ASCVD or major ASCVD risk factors.

Safety

Juxtapid has a Boxed Warning regarding the risk of hepatotoxicity.¹ Juxtapid may cause elevations in liver transaminases. Also, Juxtapid increases hepatic fat (hepatic steatosis) with or without concomitant increases in transaminases. Due to the risk of hepatotoxicity, Juxtapid is available only through a Risk Mitigation and Strategy Program. Juxtapid is a Pregnancy Category X medication and may cause fetal harm when given to a pregnant woman based on findings suggesting teratogenicity in animals. Females of reproductive potential should obtain a negative pregnancy test before Juxtapid initiation and should utilize effective contraception during Juxtapid use. Juxtapid is associated with gastrointestinal (GI) adverse events (AEs), which occurred in 93% of patients (n = 27/29). GI AEs included diarrhea (79%), nausea (65%), dyspepsia (38%), vomiting (34%), and abdominal pain (34%). Postmarketing reports regarding severe diarrhea have been associated with use of Juxtapid which have involved hospitalization of patients due to diarrhea-related complications such as volume depletion.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Juxtapid. All approvals are provided for the duration noted below. A patient who has previously met Initial Therapy criteria for Juxtapid for the requested indication under the Coverage Review Department and is currently receiving Juxtapid is only required to meet continuation of therapy criteria (i.e., currently receiving therapy). If past criteria has not been met under the Coverage Review Department and the patient is currently receiving Juxtapid, or is restarting Juxtapid, Initial Therapy criteria must be met.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Juxtapid is recommended in those who meet the following criteria:

FDA-Approved Indication

52. Homozygous Familial Hypercholesterolemia (HoFH). Approve for 1 year if the patient meets ONE of the following (A or B):

3. Initial Therapy. Approve if the patient meets ALL of the following (i, ii, iii, and iv):

i. Patient is ≥ 18 years of age; AND

ii. Patient meets ONE of the following (a, b, or c):

a) Patient has phenotypic confirmation of homozygous familial hypercholesterolemia; OR
Note: Examples include pathogenic variants at the low-density lipoprotein receptor (LDLR), apolipoprotein B (apo B), proprotein convertase subtilisin kexin type 9 (PCSK9), or low-density lipoprotein receptor adaptor protein 1 (LDLRAP1) gene.

b) Patient has an untreated low-density lipoprotein cholesterol (LDL-C) level > 400 mg/dL AND meets ONE of the following [(1) or (2)]:

Note: Untreated refers to prior therapy with any antihyperlipidemic agent.

(1) Patient had clinical manifestation of homozygous familial hypercholesterolemia before 10 years of age; OR

Note: Clinical manifestations of homozygous familial hypercholesterolemia are cutaneous xanthomas, tendon xanthomas, arcus cornea, tuberous xanthomas, or xanthelasma.

(2) At least one parent of the patient had untreated LDL-C levels or total cholesterol levels consistent with familial hypercholesterolemia; OR

Note: An example of familial hypercholesterolemia is an untreated low-density LDL-C level ≥ 190 mg/dL and/or an untreated total cholesterol level > 250 mg/dL.

c) Patient has a treated LDL-C level ≥ 300 mg/dL AND meets ONE of the following [(1) or (2)]:

Note: Treated refers to after therapy with at least one antihyperlipidemic agent. Some examples of antihyperlipidemic agents include statins (e.g., atorvastatin, rosuvastatin, lovastatin, simvastatin, pravastatin), ezetimibe, PCSK9 inhibitors (i.e., Repatha [evolocumab subcutaneous injection], Praluent [alirocumab subcutaneous injection]), and Evkeeza (evinacumab-dgnb intravenous infusion).

(1) Patient had clinical manifestations of homozygous familial hypercholesterolemia before 10 years of age; OR

Note: Examples of clinical manifestations of homozygous familial hypercholesterolemia are cutaneous xanthomas, tendon xanthomas, arcus cornea, tuberous xanthomas or xanthelasma.

(2) At least one parent of the patient had untreated LDL-C levels or total cholesterol levels consistent with familial hypercholesterolemia; AND

Note: An example of familial hypercholesterolemia is an untreated LDL-C ≥ 190 mg/dL and/or an untreated total cholesterol > 250 mg/dL.

iii. Patient meets ONE of the following (a or b):

a) Patient meets BOTH of the following [(1) and (2)]:

(1) Patient has tried at least one proprotein convertase subtilisin kexin type 9 (PCSK9) inhibitor for ≥ 8 continuous weeks; AND

Note: Examples of PCSK9 inhibitors include Repatha (evolocumab subcutaneous injection) and Praluent (alirocumab subcutaneous injection).

(2) LDL-C level after this PCSK9 inhibitor therapy remains ≥ 70 mg/dL; OR

b) Patient is known to have two LDL-receptor negative alleles; AND

iv. Patient meets ONE of the following (a or b):

a) Patient meets ALL of the following [(1), (2), and (3)]:

- (4) Patient has tried one high-intensity statin therapy (i.e., atorvastatin $\geq$ 40 mg daily; rosuvastatin $\geq$ 20 mg daily [as a single entity or as a combination product]); AND
- (5) Patient has tried one high-intensity statin along with ezetimibe (as a single-entity or as a combination product) for $\geq$ 8 continuous weeks; AND
- (6) Low-density lipoprotein cholesterol level after this treatment regimen remains $\geq$ 70 mg/dL; OR
- b) Patient has been determined to be statin intolerant by meeting ONE of the following [(1) or (2)]:
 - (1) Patient experienced statin-related rhabdomyolysis; OR
Note: Rhabdomyolysis is statin-induced muscle breakdown that is associated with markedly elevated creatine kinase levels (at least 10 times the upper limit of normal), along with evidence of end organ damage which can include signs of acute renal injury (noted by substantial increases in serum creatinine [Scr] levels [$a \geq 0.5$ mg/dL increase in Scr or doubling of the Scr] and/or myoglobinuria [myoglobin present in urine]).
 - (2) Patient meets ALL of the following [(a), (b), and (c)]:
 - (a) Patient experienced skeletal-related muscle symptoms; AND
Note: Examples of skeletal-related muscle symptoms include myopathy (muscle weakness) or myalgia (muscle aches, soreness, stiffness, or tenderness).
 - (b) The skeletal-muscle related symptoms occurred while receiving separate trials of both atorvastatin and rosuvastatin (as single-entity or combination products); AND
 - (c) When receiving separate trials of both atorvastatin and rosuvastatin (as single-entity or as combination products), the skeletal-related muscle symptoms resolved upon discontinuation of each respective statin therapy (atorvastatin and rosuvastatin); OR
Note: Examples of skeletal-related muscle symptoms include myopathy and myalgia.
- 4. Patient Currently Receiving Juxtapid. Approve if according to the prescriber, the patient has experienced a response to therapy.
Note: Examples of a response to therapy include decreasing low-density lipoprotein cholesterol (LDL-C), total cholesterol, non-high-density lipoprotein (non-HDL-C), or apolipoprotein B levels.
Note: If the patient is currently receiving the requested therapy but has not previously received approval of Juxtapid for this specific indication through the Coverage Review Department, review under criteria for Initial Therapy. If the patient is restarting therapy with Juxtapid, Initial Therapy criteria must be met.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Juxtapid is not recommended in the following situations:

- 51. **Heterozygous Familial Hypercholesterolemia (HeFH).** The safety and effectiveness of Juxtapid have not been established in patients with hypercholesterolemia who do not have HoFH, including those with HeFH.¹
- 52. **Hyperlipidemia.** The safety and efficacy of Juxtapid have not been established in patients with hypercholesterolemia who do not have HoFH.¹
Note: This is not associated with homozygous familial hypercholesterolemia and may be referred to as combined hyperlipidemia, hypercholesterolemia (pure, primary), mixed dyslipidemia, or increased/elevated low-density lipoprotein cholesterol (LDL-C) levels.

53. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Human Immunodeficiency Virus – Apretude Prior Authorization Policy

- Apretude (cabotegravir intramuscular injection – ViiV)

REVIEW DATE: 01/24/2024; selected revision 06/05/2024

OVERVIEW

Apretude, a human immunodeficiency virus-1 (HIV-1) integrase strand transfer inhibitor (INSTI), is indicated for **pre-exposure prophylaxis (PrEP)** in at-risk adults and adolescents weighing ≥ 35 kg to reduce the risk of sexually acquired HIV-1 infection.¹ Individuals must have a negative HIV-1 test prior to initiating Apretude (with or without an oral lead-in with Vocabria® [cabotegravir tablets]) for HIV-1 PrEP. All individuals should be screened for HIV-1 infection prior to each injection of Apretude.

Dosing

Apretude is administered by intramuscular (IM) gluteal injections and must be given by a healthcare provider. Vocabria may be administered for approximately 1 month prior to Apretude (Table 1) or the patient may proceed directly to Apretude without an oral lead-in (Table 2). If an oral lead-in is used, Apretude should be administered on the last day of oral lead-in or within 3 days thereafter (Table 1). Note: Vocabria is only (and will only ever be) available from the manufacturer.

Initial dosing: The recommended initiation dose of Apretude is two, single 600 mg IM injections, given 1 month apart for 2 consecutive months (Months 1 and 2 if no oral lead-in is used [Months 2 and 3 if oral lead-in is used]).¹ After the initiation injection doses, the recommended continuation dose of Apretude is a single 600 mg IM injection every 2 months (Q2M) [starting at Month 4 if no oral-lead in is used or Month 5 if oral lead-in is used]. Apretude may be given up to 7 days before or after the date of the scheduled injection.

Table 1. Recommended Dosing Schedule (with Oral Lead-in) for PrEP.¹

PrEP – Pre-exposure prophylaxis; IM – Intramuscular; Q2M – Every 2 months; QD – Once daily; ^a Should be administered on the last day of oral lead-in or within 3 days thereafter; ^b Individuals may be given Apretude up to 7 days before or after the date the individual is scheduled to receive the injections.

Table 2. Recommended Dosing Schedule (Direct to Injection) for PrEP.¹

PrEP – Pre-exposure prophylaxis; IM – Intramuscular; Q2M – Every 2 months; ^a Individuals may be given Apretude up to 7 days before or after the date the individual is scheduled to receive the injections.

Adherence to the injection dosing schedule is strongly recommended. Individuals who miss a scheduled injection visit should be clinically reassessed to ensure resumption of Apretude remains appropriate.

Planned Missed Injections: If an individual plans to miss a scheduled (Q2M) continuation injection visit by > 7 days, take Vocabria 30 mg once daily (QD) for a duration of up to 2 months to replace one missed scheduled (Q2M) injection. The first dose of Vocabria should be taken approximately 2 months after the last injection dose of Apretude. Restart Apretude on the day Vocabria dosing completes or within 3 days (Table 3). For Vocabria durations > 2 months, an alternative oral regimen is recommended.

Unplanned Missed Injections: If a scheduled injection visit is missed or delayed by > 7 days and oral dosing has not been taken in the interim, clinically reassess the individual to determine if resumption of Apretude remains appropriate (if the injection schedule will be continued, see Table 3).

Table 3. Apretude Dosing Recommendations After Missed Injections.¹
Q2M – Every 2 months.

Dose modifications for Apretude are needed when administered with rifabutin. When rifabutin is started before or concomitantly with the first initiation injection of Apretude, the recommended dosing of Apretude is one 600 mg injection, followed 2 weeks later by a second 600 mg initiation injection and monthly thereafter while on rifabutin. When rifabutin is started at the time of the second initiation injection or later, the recommended dosing schedule of Apretude is 600 mg monthly while on rifabutin. After stopping rifabutin, the recommended dosing schedule of Apretude is 600 mg Q2M.

Guidelines

Apretude has been incorporated into the US Public Health Service PrEP for the Prevention of HIV Infection in the US Clinical Practice Guidelines (December 2021).² The update was published just prior to the FDA approval of Apretude. A guideline available from the International Antiviral Society-USA (IAS-USA) [December 2022] provides similar guidance to the US Public Health Services guidelines.³ The World Health Organization (WHO) published a guideline on Apretude for PrEP in 2022 to serve as a supplement to their other oral PrEP recommendations.⁴ These guidelines are intended for a broader, world-wide audience, but generally echo the US Public Health Service PrEP and IAS-USA guideline recommendations. Table 4 provides a summary of the recommendations for daily oral PrEP and Apretude (every 2 months).

Table 4. US Public Health Service PrEP Recommendations (December 2021).²

Table 4 (continued). US Public Health Service PrEP Recommendations (December 2021).²

PrEP – Pre-exposure prophylaxis; ^a Conditioned on FDA-approval at the time of guideline publication; HIV – Human immunodeficiency virus; FTC/TDF – Emtricitabine/tenofovir disoproxil fumarate; IDU – Injection drug user(s); * Individuals assigned male sex at birth whose gender identity is male; † Individuals assigned male sex at birth whose gender identity is female; ‡ Individuals assigned female sex at birth whose gender identity is female.

The US Public Health Service Guidelines also make the following points related to monitoring for PrEP.² Prior to prescribing PrEP, acute and chronic HIV infection must be excluded by symptom and HIV testing must be performed immediately before any PrEP regimen is started (IA). Clinicians should document a negative HIV test result within the week before initiating (or reinitiating) PrEP medications, ideally with an antigen/antibody test conducted by a laboratory. The required HIV test prior to initiation of PrEP can be accomplished in one of two ways: 1) drawing blood and sending the specimen to a laboratory for an antigen/antibody test or 2) performing a rapid, point-of-care, FDA-approved, fingerstick antigen/antibody blood test. For PrEP, rapid tests that use oral fluid should not be used to screen for HIV infection because they are less sensitive for the detection of acute or recent infection than blood tests. HIV infection should be assessed every 2 months for patients receiving Apretude so that individuals with incident infection do not continue taking PrEP. When PrEP is prescribed, clinicians should provide access to support for medication adherence and continuation in follow-up PrEP care (IIA) and additional proven effective risk-reduction services to enable the use of PrEP in combination with other effective prevention methods to reduce risk for sexual acquisition of sexually transmitted infections or blood borne bacterial and viral infections through intravenous drug use (IIIA).

Guidelines from the IAS-USA state that for Apretude, HIV testing at initiation and at all visits should ideally include an HIV RNA tests with a lower limit of quantification of ≤ 50 copies/mL AND a laboratory-based antigen-antibody test.³ If RNA testing is not available, Apretude can still be considered using antigen/antibody screening only. Results of such testing do not need to be available to provide injections.

The WHO guidelines for Apretude in PrEP enforce that HIV testing prior to offering Apretude is required and should be continued prior to each injection with Apretude.⁴ Only individuals who are HIV-negative should be initiated on PrEP. HIV testing can be conducted using quality-assured serology assays (i.e., rapid diagnostic tests and enzyme immunoassays).

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Apretude. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Apretude as well as the monitoring required for adverse events and long-term efficacy, approval requires Apretude to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Apretude is recommended in those who meet the following criteria:

FDA-Approved Indication

63. Pre-exposure Prophylaxis (PrEP) of Human Immunodeficiency Virus (HIV)-1 Infection.

Approve for 2 months if the patient meets ALL of the following (A, B, C, and D):

A) Patient is ≥ 35 kg; AND

B) Patient meets BOTH of the following conditions (i and ii):

01/24/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

- i. The medication will be administered only if the patient has a negative HIV-1 test result ≤ 1 week prior to the dose of Apretude; AND
- ii. The medication will be administered only if the patient has no signs or symptoms of acute HIV infection, according to the prescriber; AND
- C) The medication is prescribed as part of a comprehensive HIV-1 prevention strategy (i.e., adherence to administration schedule and safer sex practices, including condoms); AND
- D) The medication is prescribed by or in consultation with a physician who specializes in the management of HIV infection.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Apretude is not recommended in the following situations:

180. Treatment of Human Immunodeficiency Virus (HIV). Apretude is not indicated for the treatment of HIV. It is inadequate therapy for established HIV infection and use in persons with early HIV infection may encourage resistance of one or more of the PrEP medications.²

181. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Human Immunodeficiency Virus – Cabenuva Prior Authorization Policy

- Cabenuva® (cabotegravir extended-release intramuscular injection; rilpivirine extended-release intramuscular injection, co-packaged – ViiV/GlaxoSmithKline)

REVIEW DATE: 02/07/2024

OVERVIEW

Cabenuva is a two-drug co-packaged product of cabotegravir, a human immunodeficiency virus type-1 (HIV-1) integrase strand-transfer inhibitor, and rilpivirine, an HIV-1 non-nucleoside reverse transcriptase inhibitor.¹ It is indicated as a complete regimen for the treatment of **HIV-1 infection** in patients ≥ 12 years of age and ≥ 35 kg to replace their current antiretroviral regimen in those who are virologically suppressed (HIV-1 RNA < 50 copies/mL) on a stable antiretroviral regimen with no history of treatment failure and with no known or suspected resistance to cabotegravir or rilpivirine.¹

Dosing

Cabenuva must be administered by a healthcare professional. Prior to starting Cabenuva, healthcare professionals should carefully select patients who agree to the required monthly injection dosing schedule and counsel patients about the importance of adherence to scheduled dosing visits to help maintain viral suppression and reduce the risk of viral rebound and potential development of resistance with missed doses.¹

Oral lead-in with Vocabria® (cabotegravir tablets) + Edurant® (rilpivirine tablets) may be used for approximately 1 month (at least 28 days) prior to the initiation of Cabenuva to assess the tolerability of cabotegravir and rilpivirine. Cabenuva may be administered as a once-monthly injection or once every 2-month injection. Table 1 provides the recommended oral lead-in and monthly injection dosing schedule. Table 2 provides the recommended oral lead-in and every 2-month injection dosing schedule.

Table 1. Recommended Oral Lead-In and Monthly Intramuscular Injection Dosing Schedule.¹

QD – Once daily.

Table 2. Recommended Oral Lead-In and Every 2-Month Intramuscular Injection Dosing Schedule.¹

QD – Once daily.

Guidelines

The Department of Health and Human Services (DHHS) Guidelines for the Use of Antiviral Agents in Adults and Adolescents with HIV (December 6, 2023) recognize Cabenuva as a long-acting antiretroviral regimen that is an optimization option for patients who are engaged with their health care providers, virologically suppressed on oral therapy for 3 to 6 months, and who agree to make the frequent clinic visits needed.⁵ Both FDA-approved dosing regimens are appropriate for Cabenuva in virally suppressed patients (once monthly or every 2-month dosing and with or without oral lead-in). The Guidelines point out that the tablet formulation of cabotegravir (Vocabria®) is only available through the manufacturer, not in community pharmacies. Cabenuva is not recommended as initial therapy for people with HIV because of the lack of data supporting efficacy in this patient population.

International Antiviral Society-USA (IAS-USA) Recommendations on Antiretroviral Drugs for Treatment and Prevention of HIV Infection in Adults (2022) have similar recommendations to the DHHS guidelines for Cabenuva.⁷ In individuals with no of treatment failure and no known or suspected resistance to either agent, Cabenuva is an option. Cabenuva is noted to give greater patient satisfaction vs. oral antiretrovirals

(ARVs) to those interested in non-oral options for treatment because of privacy, stigma, or convenience reasons. Both approved dosing regimens (with and without oral lead-in) are considered acceptable based on patient preference. If scheduled doses of Cabenuva are missed, resumption of therapy should follow the Prescribing Information. Cabenuva is not recommended for initial therapy in ARV-naïve individuals.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Cabenuva. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Cabenuva as well as the monitoring required for adverse events and long-term efficacy, initial approval requires Cabenuva to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Documentation: Documentation is required for use of Cabenuva as noted in the criteria as **[documentation required]**. Documentation may include, but is not limited to, chart notes, prescription claims records, prescription receipts, and/or other information.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Cabenuva is recommended in those who meet the following criteria:

FDA-Approved Indication

1. Human Immunodeficiency Virus (HIV)-1, Treatment. Approve for 1 year if the patient meets ONE of the following (A or B):

E) Initial Therapy. Approve if the patient meets ALL of the following (i, ii, iii, iv, and v):

- i.** Patient is ≥ 12 years of age; AND
- ii.** Patient weighs ≥ 35 kg; AND
- iii.** Patient has HIV-1 RNA < 50 copies/mL (viral suppression) **[documentation required]**; AND
- iv.** Prior to initiating Cabenuva or 1 month lead-in with Vocabria (cabotegravir tablets), the patient was treated with a stable regimen (≥ 3 months) of antiretrovirals for HIV-1 **[documentation required]**; AND
- v.** The medication is prescribed by or in consultation with a physician who specializes in the treatment of HIV infection.

F) Patient is Currently Receiving Cabenuva. Approve if the patient has HIV-1 RNA < 50 copies/mL (viral suppression) **[documentation required]**.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Cabenuva is not recommended in the following situations:

182. Pre-Exposure Prophylaxis (PrEP) of Human Immunodeficiency Virus (HIV)-1 Infection. Cabenuva is not indicated for the prevention of HIV.

183. Co-administration with Antiretrovirals for Human Immunodeficiency Virus (HIV) Treatment. Because Cabenuva is a complete regimen, co-administration with other antiretroviral medications for the treatment of HIV-1 infection is not recommended.¹

- 184. Human Immunodeficiency Virus (HIV)-2 Infection.** Cabenuva is not indicated in patients with HIV-2 infection.¹ The Department of Health and Human Services guidelines further note that HIV-2 is intrinsically resistant to non-nucleoside reverse transcriptase inhibitors, therefore, Cabenuva is not recommended for people with HIV-2.⁵
- 185.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Human Immunodeficiency Virus – Rukobia Prior Authorization Policy

- Rukobia™ (fostemsavir extended-release tablets – ViiV/GlaxoSmithKline)

REVIEW DATE: 07/17/2024

OVERVIEW

Rukobia is a human immunodeficiency virus-1 (HIV-1) gp120-directed attachment inhibitor.¹ It is indicated in combination with other antiretroviral(s) [ARVs] for the treatment of HIV-1 infection in heavily treatment-experienced adults with **multidrug-resistant HIV-1 infection** failing their current ARV regimen due to resistance, intolerance, or safety considerations.

Clinical Efficacy

The efficacy of Rukobia was established in one ongoing, Phase III, multicenter, 96-week pivotal study in heavily treatment-experienced adults with HIV-1 infection failing their current ARV regimen (BRIGHT; n = 371).^{2,5} Eligible patients were ≥ 18 years of age and had failure of their current ARV regimen (baseline HIV-1 RNA ≥ 400 copies/mL), with no viable ARV combination therapy due to exhaustion of a least four of six ARV classes (i.e., nucleoside reverse transcriptase inhibitors, non-nucleoside reverse transcriptase inhibitors, integrase inhibitors, protease inhibitors, CCR5 antagonists, and entry inhibitors). Exhaustion was defined as the elimination of all ARVs within a given class as a fully active option to pair with Rukobia because of resistance, previous adverse events, or unwillingness to use Fuzeon® (enfuvirtide subcutaneous injection). Patients were assigned to one of two cohorts, “randomized” or “non-randomized”, based on the number of fully active available ARVs with which to construct an optimized background regimen. Patients in the randomized cohort had one or two available fully active ARVs while those in the non-randomized cohort had no available fully active ARVs. There were 15 patients who received Trogarzo® (ibalizumab-uiyk intravenous injection) in combination with Rukobia in the original study (after approval of Rukobia, in 2018, 6 patients in the randomized cohort added Trogarzo to their optimized background therapy). At Week 48 (all patients on Rukobia + optimized background therapy), 54% of patients achieved viral suppression (HIV-1 RNA < 40 copies/mL) and CD4 T-cell count increased to a mean of 139 cells/mm³ (median baseline 99 cells/mm³). At Week 96, viral suppression was maintained or improved (60% of patients in the randomized cohort and 37% of patients in the non-randomized cohort).⁵ Virologic response rates (in the intent-to-treat population) at Week 240 decreased to 45% in the randomized cohort and to 22% in the non-randomized cohort; however, this included 24 patients (n = 19 in the randomized cohort and n = 5 in the non-randomized cohort) who did not have virologic data due to Coronavirus-19-related disruptions to care. At Week 240, in the observed analysis, HIV-1 RNA was < 40 copies/mL in 82% of patients in the randomized cohort and in 66% of patients in the non-randomized cohort and was < 400 copies/mL in 95% and 80% of patients in the randomized and non-randomized cohorts, respectively. Mean CD4 T-cell count increased through Week 192 in the randomized cohort and remained similar at Week 240; in the non-randomized cohort, CD4 T-cell count increased through Week 240. A safety analysis reported additional findings.⁷ At Week 102, 58% of patients with CD4 T-cell count < 200 cells/mm³ at baseline had on-treatment CD4 T-cell count reported at Week 192, and 75% of these patients had a CD4 T-cell count ≥ 200 cells/mm². In addition, acquired immunodeficiency syndrome-defining events were lower among patients with CD4 T-cell count ≥ 200 cells/mm³ vs. < 200 cells/mm³.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Guidelines

According to the Department of Health and Human Services Guidelines (February 27, 2024) for the use of antiviral agents in adults and adolescents with HIV infection, treatment-experienced patients with ongoing detectable viremia who lack sufficient treatment options to construct a fully suppressive regimen may be candidates for Trogarzo, Rukobia, or Sunlenca® (lenacapavir tablets/subcutaneous injection).³ Patients who continue to have detectable viremia and who lack sufficient treatment options to construct a fully suppressive regimen may also be candidates for research studies or expanded access programs, or they may qualify for single-patient access to an investigational new drug as specified in FDA regulations. The goal of therapy is viral resuppression, if possible; otherwise, to keep the viral load as low as possible and CD4 T-cell count as high as possible. CD4 T-cell count is recommended to be monitored at entry into care, when switching or modifying ARVs, and then every 3, 6, or 12 months depending on CD4 T-cell count and the duration of viral suppression. The CD4 count response to ARV therapy varies widely, but a poor CD4 response in a patient with viral suppression is rarely an indication for modifying a treatment regimen.

The International Antiviral Society-USA recommendations (2022) for the treatment and prevention of HIV in adults recognize Rukobia in the setting of integrase strand-transfer inhibitor (INSTI) resistance. If INSTI resistance is relatively limited and a new antiviral regimen is to include an INSTI, the regimen should also include at least one and preferably two other fully active drugs, optimally from drug classes not previously used which may include among other agents, Rukobia.⁴

Consensus recommendations for the use of novel ARVs in individuals with HIV who are heavily treatment-experienced and/or have multidrug-resistant HIV-1 endorsed by the American Academy of HIV Medicine and the American College of Clinical Pharmacology (2024) recommend adding Rukobia to an optimized background regimen that includes at least one other active drug in patients with multidrug resistant HIV-1 who are heavily treatment-experienced and are unable to achieve or maintain viral suppression on their current ARV regimen.⁸ If an active drug cannot be included in the optimized background regimen, then the regimen should include partially active agents (preferably several). Prior treatment with Trogarzo should not impact candidacy for Rukobia.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Rukobia. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Rukobia as well as the monitoring required for adverse events and long-term efficacy, initial approval requires Rukobia to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Rukobia is recommended in those who meet the following criteria:

FDA-Approved Indication

64. Human Immunodeficiency Virus (HIV)-1 Infection. Approve for the duration noted if the patient meets ONE of the following (A or B):

A) Initial Therapy. Approve for 6 months if the patient meets ALL of the following (i, ii, iii, iv, and v):

- i.** Patient is ≥ 18 years of age; AND
- ii.** According to the prescriber, the patient is failing a current antiretroviral regimen for HIV; AND
- iii.** According to the prescriber, the patient has exhausted at least FOUR of the following antiretroviral classes defined as elimination of all antiretrovirals within a given class due to demonstrated or projected resistance to the agent(s) in that class OR due to significant intolerance (FOUR of a, b, c, d, e, or f):
 - a)** Nucleoside reverse transcriptase inhibitor; OR
Note: Examples of nucleoside reverse transcriptase inhibitors include abacavir, didanosine, emtricitabine, lamivudine, stavudine, tenofovir disoproxil fumarate, tenofovir alafenamide, zidovudine.
 - b)** Non-nucleoside reverse transcriptase inhibitor; OR
Note: Examples of non-nucleoside reverse transcriptase inhibitor include delavirdine, efavirenz, etravirine, nevirapine, nevirapine XR, rilpivirine.
 - c)** Protease inhibitor; OR
Note: Examples of protease inhibitors include atazanavir, darunavir, fosamprenavir, indinavir, nelfinavir, ritonavir, saquinavir, tipranavir.
 - d)** Fusion inhibitor; OR
Note: Examples of fusion inhibitors include Fuzeon (enfuvirtide subcutaneous injection).
 - e)** Integrase strand transfer inhibitor; OR
Note: Examples of integrase strand-transfer inhibitors include raltegravir, dolutegravir, elvitegravir.
 - f)** CCR5 antagonist; AND
Note: Examples of CCR5 antagonists include Selzentry (maraviroc tablets).
- iv.** The medication will be taken in combination with an optimized antiviral background regimen including one or more other antiretroviral agents; AND
- v.** The medication is prescribed by or in consultation with a physician who specializes in the treatment of HIV infection.

B) Patient is Currently Receiving Rukobia. Approve for 1 year if the patient meets BOTH of the following (i and ii):

- i.** The medication will continue to be taken in combination with an optimized antiviral background regimen including one or more other antiretroviral agents; AND
- ii.** Patient has responded to a Rukobia-containing regimen, as determined by the prescriber.
Note: Examples of a response are HIV RNA < 40 cells/mm³, HIV-1 RNA ≥ 0.5 log₁₀ reduction from baseline in viral load, improvement or stabilization of CD4 T-cell count.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Rukobia is not recommended in the following situations:

- 186.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Human Immunodeficiency Virus – Sunlenca Prior Authorization Policy

- Sunlenca® (lenacapavir tablets and subcutaneous injection – Gilead)

REVIEW DATE: 01/03/2024; selected revision 07/17/2024

OVERVIEW

Sunlenca, a human immunodeficiency virus-1 (HIV-1) capsid inhibitor, is indicated in combination with other antiretroviral(s) for the treatment of **multidrug resistant HIV-1 infection** in heavily treatment-experienced adults failing their current antiretroviral regimen due to resistance, intolerance, or safety considerations.¹ Of note, Sunlenca is also available as tablets which are not addressed in this policy.

Clinical Efficacy

The efficacy of Sunlenca was evaluated in one Phase II/III, randomized, double-blind, placebo-controlled, multicenter, pivotal study in patients with multidrug resistant HIV-1.² Eligible patients had documented resistance to two or more agents from three of four main antiretroviral classes (nucleoside reverse transcriptase inhibitor [NRTI], non-nucleoside reverse transcriptase inhibitor [NNRTI], protease inhibitor, and integrase strand-transfer inhibitor [INSTI]) and two or fewer active antiretrovirals from the four main classes that could be effectively combined for optimized background therapy.

Guidelines

According to the Department of Health and Human Services Guidelines (February 27, 2024) for the use of antiviral agents in adults and adolescents with HIV infection, treatment-experienced patients with ongoing detectable viremia who lack sufficient treatment options to construct a fully suppressive regimen may be candidates for Trogarzo® (ibalizumab-uiyk intravenous infusion), Rukobia™ (fostemsavir extended-release tablets), or Sunlenca.⁴ Patients who continue to have detectable viremia and who lack sufficient treatment options to construct a fully suppressive regimen may also be candidates for research studies or expanded access programs, or they may qualify for single-patient access to an investigational new drug as specified in FDA regulations. The goal of therapy is viral resuppression, if possible; otherwise, to keep the viral load as low as possible and CD4 T-cell count as high as possible. The CD4 T-cell count is used to assess a patient's immunologic response to treatment. CD4 T-cell count is recommended to be monitored at entry into care, when switching or modifying ARVs, and then every 3, 6, or 12 months depending on CD4 T-cell count and the duration of viral suppression. The CD4 T-cell count response to ARV therapy varies widely, but a poor CD4 T-cell response in a patient with viral suppression is rarely an indication for modifying a treatment regimen. For people with multidrug-resistant HIV-2, Trogarzo and Sunlenca may be considered based on *in vitro* data. Optimal treatment strategies for individuals with HIV-2 are not defined.

The International Antiviral Society-USA (December 2022) provides some guidance on patients with viral failure; Sunlenca is mentioned in patients with INSTI resistance as a product under FDA review.⁵ Management of INSTI resistance can be difficult and guidance from an expert in HIV drug resistance is recommended for selection of the optimal regimen. If INSTI resistance is relatively limited, and a new regimen is to include an INSTI, dolutegravir should be administered twice daily. The regimen should also include at least one, and preferably two other fully active drugs, optimally from drug classes not previously used. Therapies may include Rukobia, Sunlenca, Selzentry® (maraviroc tablets, generic and oral solution), Trogarzo, or Fuzeon® (enfuvirtide SC injection).

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Sunlenca. All approvals are provided for the duration noted below. Because of the specialized skills required for evaluation and diagnosis of patients treated with Sunlenca as well as the monitoring required for adverse events and long-term efficacy, approval requires Sunlenca to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Sunlenca is recommended in those who meet the following criteria:

FDA-Approved Indication

65. Human Immunodeficiency Virus (HIV)-1 Infection, Treatment. Approve for the duration noted if the patient meets ONE of the following (A or B):

A) Initial Therapy. Approve for 6 months if the patient meets ALL of the following (i, ii, iii, iv, and v):

iii. Patient is ≥ 18 years of age; AND

iv. According to the prescriber, the patient is failing a current antiretroviral regimen for HIV; AND

iii. According to the prescriber, the patient has resistance to two or more agents from at least THREE of the following antiviral classes (a, b, c, d):

a) Nucleoside reverse transcriptase inhibitor;

Note: Examples of nucleoside reverse transcriptase inhibitors include abacavir, didanosine, emtricitabine, lamivudine, stavudine, tenofovir disoproxil fumarate, tenofovir alafenamide, zidovudine.

b) Non-nucleoside reverse transcriptase inhibitor;

Note: Examples of non-nucleoside reverse transcriptase inhibitors include delavirdine, efavirenz, etravirine, nevirapine, nevirapine XR, rilpivirine.

c) Protease inhibitor;

Note: Examples of protease inhibitors include atazanavir, darunavir, fosamprenavir, indinavir, nelfinavir, ritonavir, saquinavir, tipranavir.

d) Integrase strand transfer inhibitor; AND

Note: Examples of integrase strand transfer inhibitors include raltegravir, dolutegravir, elvitegravir.

iv. The medication will be taken in combination with an optimized antiviral background regimen including one or more other antiretroviral agents; AND

v. The medication is prescribed by or in consultation with a physician who specializes in the treatment of HIV infection.

C) Patient is Currently Receiving Sunlenca. Approve for 1 year if the patient meets BOTH of the following (i and ii):

iii. The medication will continue to be taken in combination with an optimized antiviral background regimen including one or more other antiretroviral agents; AND

iv. Patient has responded to a Sunlenca-containing regimen, as determined by the prescriber.

Note: Examples of a response are HIV RNA < 50 cells/mm³, HIV-1 RNA ≥ 0.5 log₁₀ reduction from baseline in viral load, improvement or stabilization of CD4 T-cell count.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

01/03/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

Coverage of Sunlenca is not recommended in the following situations:

- 187. Pre-Exposure Prophylaxis (PrEP) of Human Immunodeficiency Virus (HIV).** Sunlenca is not approved for this indication; however, it is under investigation in two Phase III, unpublished, and ongoing clinical trials for PrEP (PURPOSE 1 and PURPOSE 2).^{7,8}
- 188. Human Immunodeficiency Virus (HIV), Treatment in Treatment-Naïve Patients.** Sunlenca is not approved for this indication; however, it is under investigation in one Phase II ongoing clinical trial in treatment-naïve adults with HIV-1 (CALIBRATE).³
- 189.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Human Immunodeficiency Virus – Trogarzo Prior Authorization Policy

- Trogarzo® (ibalizumab-uiyk intravenous infusion – Theratechnologies)

REVIEW DATE: 03/27/2024; selected revision 07/17/2024

OVERVIEW

Trogarzo is a long-acting humanized immunoglobulin G4 monoclonal antibody indicated in combination with other antiretroviral(s) for the treatment of **human immunodeficiency virus-1 (HIV-1) infection** in heavily treatment-experienced adults with multidrug resistant HIV-1 infection failing their current antiretroviral regimen.¹ Patients should receive a single intravenous loading dose of 2,000 mg followed by a maintenance dose of 800 mg once every 2 weeks. The loading dose and maintenance doses of Trogarzo can be administered as a diluted intravenous (IV) infusion or undiluted IV push.

Disease Overview

Multiclass or three-class drug resistant HIV-1 infection is usually defined as the presence of phenotypic or genotypic resistance to at least one drug in each of the following three classes: the nucleoside reverse transcriptase inhibitors, non-nucleoside reverse transcriptase inhibitors, and protease inhibitors classes.² Trogarzo blocks HIV-1 from infecting CD4+ T-cells by binding to domain 2 of CD4.¹ This interferes with post-attachment steps required for the entry of HIV-1 virus particles into host cells and prevents the viral transmission that occurs via cell-cell fusion. The binding specificity to domain 2 of CD4 allows Trogarzo to block viral entry into host cells without causing immunosuppression. There is no antagonism with other antiretrovirals. In the pivotal trial for Trogarzo, all patients had documented resistance to at least one antiretroviral from the nucleoside reverse transcriptase inhibitor, non-nucleoside reverse transcriptase inhibitor, and protease inhibitor classes.

Guidelines

According to the Department of Health and Human Services Guidelines (February 27, 2024) for the use of antiviral agents in adults and adolescents with HIV infection, treatment-experienced patients with ongoing detectable viremia who lack sufficient treatment options to construct a fully suppressive regimen may be candidates for Trogarzo, Rukobia™ (fostemsavir extended-release tablets), or Sunlenca® (lenacapavir subcutaneous [SC] injection).⁴ The goal of therapy is viral resuppression, if possible; otherwise, to keep the viral load as low as possible and CD4 T-cell count as high as possible. The CD4 T-cell count is used to assess a patient's immunologic response to treatment. CD4 T-cell count is recommended to be monitored at entry into care, when switching or modifying ARVs, and then every 3, 6, or 12 months depending on CD4 T-cell count and the duration of viral suppression. The CD4 T-cell count response to ARV therapy varies widely, but a poor CD4 T-cell response in a patient with viral suppression is rarely an indication for modifying a treatment regimen. For people with multidrug-resistant HIV-2, Trogarzo and Sunlenca may be considered based on *in vitro* data. Optimal treatment strategies for individuals with HIV-2 are not defined.

The International Antiviral Society-USA (December 2022) provides some guidance on patients with viral failure.⁴ The regimen should also include at least one, and preferably two other fully active drugs, optimally from drug classes not previously used. Therapies may include Rukobia, Selzentry® (maraviroc tablets, generic and oral solution), Trogarzo, or Fuzeon® (enfuvirtide SC injection).

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Trogarzo. All approvals are provided for the duration noted below. In cases where the approval is authorized in months, 1 month is equal to 30 days. Because of the specialized skills required for evaluation and diagnosis of patients treated with Trogarzo as well as the monitoring required for adverse events and long-term efficacy, initial approval requires Trogarzo to be prescribed by or in consultation with a physician who specializes in the condition being treated.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Trogarzo is recommended in those who meet the following:

FDA-Approved Indication

66. Human Immunodeficiency Virus (HIV)-1 Infection. Approve for the duration outlined below if the patient meets ONE of the following (A and B):

A) Initial Therapy. Approve for 6 months if the patient meets ALL of the following (i, ii, iii, iv, and v):

i. Patient is ≥ 18 years of age; AND

ii. According to the prescriber, the patient is failing a current antiretroviral regimen for HIV; AND

iii. Patient has multiple antiretroviral drug resistance as demonstrated by resistance to one or more antiretroviral from at least THREE of the following antiviral classes (a, b, c, d, e, f):

a) Nucleoside reverse transcriptase inhibitor;

Note: Examples of nucleoside reverse transcriptase inhibitors include but are not limited to abacavir, didanosine, emtricitabine, lamivudine, stavudine, tenofovir disoproxil fumarate, tenofovir alafenamide, zidovudine.

b) Non-nucleoside reverse transcriptase inhibitor;

Note: Examples of non-nucleoside reverse transcriptase inhibitors include but are not limited to delavirdine, efavirenz, etravirine, nevirapine, nevirapine XR, rilpivirine.

c) Protease inhibitor;

Note: Examples of protease inhibitors include but are not limited to atazanavir, darunavir, fosamprenavir, indinavir, nelfinavir, ritonavir, saquinavir, tipranavir.

d) Fusion inhibitor;

Note: An example of a fusion inhibitor includes but is not limited to Fuzeon (enfuvirtide subcutaneous injection).

e) Integrase strand transfer inhibitor;

Note: Examples of integrase strand transfer inhibitors include but are not limited to raltegravir, dolutegravir, and elvitegravir.

f) CCR5-antagonist; AND

Note: An example of a CCR5-antagonist includes but is not limited to Selzentry (maraviroc tablets).

iv. The medication will be taken in combination with an optimized antiviral background regimen including one or more other antiretroviral agents; AND

v. The medication is prescribed by or in consultation with a physician who specializes in the treatment of HIV infection.

B) Patient is Currently Receiving Trogarzo. Approve for 1 year if the patient meets BOTH of the following (i and ii):

- i. The medication will continue to be taken in combination with an optimized antiviral background regimen including one or more other antiretroviral agents; AND
- ii. Patient has responded to a Trogarzo-containing regimen, as determined by the prescriber.
Note: Examples of a response are HIV RNA < 50 cells/mm³, HIV-1 RNA $\geq 0.5 \log_{10}$ reduction from baseline in viral load, improvement or stabilization of CD4 T-cell count.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Trogarzo is not recommended in the following situations:

- 190.** Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

REVIEW DATE: 10/09/2024

OVERVIEW

Hyaluronic acid derivatives are indicated for the treatment of **pain related to knee osteoarthritis** in patients who have failed to respond adequately to conservative nonpharmacologic therapy and to simple analgesics (e.g., acetaminophen).^{1-16,43}

The use of intraarticular injections are to restore the normal properties (viscosity and elasticity) of the synovial fluid. Gel-One, Hyalgan, Supartz FX, Synvisc/Synvisc-One, Triluron, and Visco-3 are derived from rooster or chicken combs. The remaining products are derived from non-avian sources and may be useful for patients with allergies to eggs or poultry products. GenVisc 850 has data to support similarity to Supartz FX.⁹ Although retreatment data are limited, all of these products have data concerning efficacy and/or safety of repeat courses. In many cases, at least 6 months was required or a minimum of 6 months had elapsed prior to injection of a repeat course.

Table 1. Number of Injections per Course of Therapy for Intraarticular Hyaluronic Acid Derivatives.^{1-16,43*}

* Dose is for one knee. If two knees are being treated, then each knee requires a syringe or vial of product.

Guidelines

Guidelines for the management of osteoarthritis of the hand, hip, and knee are available from the **American College of Rheumatology** (2019).¹⁷ Pharmacologic therapy for knee osteoarthritis consists of acetaminophen, oral and topical non-steroidal anti-inflammatory drugs (NSAIDs), tramadol, intraarticular corticosteroid injections, duloxetine, and topical capsaicin. There is limited evidence establishing a benefit of hyaluronic acid intraarticular injections, which contributes to the conditional recommendation against use in knee osteoarthritis. However, when other alternatives have been exhausted or have failed to provide

10/09/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

satisfactory benefit, use of intraarticular hyaluronic acid injections may be viewed more favorably than offering no intervention. In the guidelines, no distinction is made between the available intraarticular hyaluronic acid products or between products with various molecular weights.

The **Osteoarthritis Research Society International** also has guidelines for knee osteoarthritis (2019).¹⁹ These guidelines note that use of intraarticular hyaluronic acid injections are conditionally recommended for patients with knee osteoarthritis. The guidelines comment on the long-term treatment effect with intraarticular hyaluronic acid injections which is associated with symptom improvement beyond 12 weeks and a more favorable safety profile than intraarticular corticosteroid injections.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of hyaluronic acid derivative intraarticular products indicated for knee osteoarthritis. All approvals are provided for one course of therapy per treated knee. Note: One month is a sufficient approval duration for one course of Durolane, Euflexxa, Gel-One, Gelsyn-3, Hymovis, Monovisc, sodium hyaluronate 1% injection, SynoJoynt, Synvisc, Synvisc-One, Triluron, TriVisc, and Visco-3; and 5 weeks is a sufficient approval duration for one course of GenVisc 850, Orthovisc, Hyalgan, and Supartz FX. Because of the specialized skills required for evaluation and diagnosis of patients treated with hyaluronic acid derivative intraarticular products as well as the specialized administration technique, approval requires these products to be administered by or under the supervision of a physician specializing in rheumatology, orthopedic surgery, or physical medicine and rehabilitation (physiatrist). Previous therapy is required to be verified by a clinician in the Coverage Review Department when noted in the criteria as **[verification of therapies required]**.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of hyaluronic acid derivative intraarticular products is recommended in those who meet the following criteria:

FDA-Approved Indication

1. **Osteoarthritis of the Knee.** Approve one course of therapy per treated knee if the patient meets ONE of the following (A or B):
 - A) **Initial Therapy.** Approve an initial course if the patient meets ALL of the following (i, ii, and iii):
 - i. Diagnosis of the knee to be treated is confirmed by radiologic evidence of knee osteoarthritis; AND
Note: Examples of radiographic evidence includes x-ray, magnetic resonance imaging (MRI), computed tomography (CT) scan, ultrasound.
 - ii. Patient has tried at least TWO of the following modalities of therapy for osteoarthritis (a, b, or c):
 - a) At least one course of physical therapy for knee osteoarthritis; OR
 - b) At least TWO of the following pharmacologic therapies [(1), (2), (3), or (4)]
[verification of therapies required]:
 - (1) Oral or topical nonsteroidal anti-inflammatory drug(s) [NSAID(s)];
Note: Examples of oral NSAIDs include naproxen, ibuprofen, celecoxib. Examples of topical NSAIDs include diclofenac solution or diclofenac gel. A trial of two or more NSAIDs (oral and/or topical) counts as one pharmacologic therapy.
 - (2) Acetaminophen;

- (3) Tramadol (Ultram/XR, generic);
- (4) Duloxetine (Cymbalta, generic); OR
- c) At least TWO injections of intraarticular corticosteroids to the affected knee; AND
- iii. The product is administered by or under the supervision of a physician specializing in rheumatology, orthopedic surgery, or physical medicine and rehabilitation (physiatrist).
- B) Patient has Already Received One or More Courses of Hyaluronic Acid Derivative in the Same Knee. Approve one repeat course if the patient meets ALL of the following (i, ii, and iii)
 - i. At least 6 months have elapsed since the last injection with any hyaluronic acid derivative; AND
 - ii. According to the prescriber, the patient had a response to the previous course of hyaluronic acid derivative therapy for osteoarthritis of the knee and now requires additional therapy for osteoarthritis symptoms; AND

Note: Examples of a response include reduced joint pain, tenderness, morning stiffness, or improved mobility.
 - iii. The product is administered by or under the supervision of a physician specializing in rheumatology, orthopedic surgery, or physical medicine and rehabilitation (physiatrist).

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of hyaluronic acid derivatives is not recommended in the following situations:

18. **Acute Ankle Sprain.** A randomized, controlled, prospective trial was conducted which assessed the use of intraarticular hyaluronic acid in acute ankle sprains.²⁰⁻²¹ Patients treated with intraarticular hyaluronic acid (n = 79) within 48 hours of injury and again on Day 4 reported a time to pain-free and disability-free return to sport of 11 days ($\pm$ 8 days) compared with 17 days ($\pm$ 8 days) for placebo ($P < 0.05$). All patients were also treated with standard of care (rest, ice, compression, and elevation). At 24 months, the placebo group experienced an increase in repeat sprains when compared with those treated with an intraarticular hyaluronic acid product (21 recurrent ankle sprains in the placebo group compared with 7 recurrent ankle sprains in the intraarticular hyaluronic acid treatment group [$P < 0.001$]) as well as a significant difference in missed days from participation in sport activity (49 days vs. 12 days for the placebo and hyaluronic acid groups, respectively; $P < 0.001$).²¹ More data are needed to determine the role of intraarticular hyaluronic acid products in the treatment of acute ankle sprains.
19. **Osteoarthritis and Other Pathologic Conditions Involving Joints Other than the Knee** (e.g., hand, hip, ankle, shoulder osteoarthritis, temporomandibular joint [TMJ], adhesive capsulitis of the shoulder, subacromial impingement). The prescribing information for these agents state in the precautions section that the safety and effectiveness of hyaluronic acid derivatives injections into joints other than the knee have not been established.¹⁻¹⁶ Due to the absence of evidence to support use of intraarticular hyaluronic acid and potential for harm, the guidelines for the management of hand, hip, and knee osteoarthritis by American College of Rheumatology (2019) do not recommend use of intraarticular hyaluronic acid in patients with hand or hip osteoarthritis.¹⁷ Small trials have also investigated intraarticular hyaluronic acid in other joints, including ankle osteoarthritis and hip osteoarthritis.²³⁻³⁸ More data are needed to determine if there is a role for intraarticular hyaluronic acid for the treatment of osteoarthritis involving other joints. A small trial (n = 70) found that intraarticular hyaluronic acid did not result in increased benefit for adhesive capsulitis of the shoulder (also known as frozen shoulder) in patients who were already receiving physical therapy.³⁹ Another small study (n = 159) did not show benefit of intraarticular hyaluronic acid over corticosteroid or placebo injections in patients with subacromial impingement.⁴⁰

20. **Pathologic Conditions of the Knee Other than Osteoarthritis** (e.g., chondromalacia patellae, osteochondritis dissecans, patellofemoral syndrome, post-anterior cruciate ligament [ACL] reconstruction). Intraarticular hyaluronic acid products are indicated in knee osteoarthritis.¹⁻¹⁶ Adequate, well-designed trials have not clearly established the use of intraarticular hyaluronic acid in other conditions of the knee.⁴¹⁻⁴²
21. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hyperhidrosis – Qbrexza Prior Authorization Policy

- Qbrexza™ (glycopyrronium cloth 2.4% for topical use – Journey Medical)

REVIEW DATE: 05/01/2024; selected revision 07/17/2024

OVERVIEW

Qbrexza, an anticholinergic, is indicated for the topical treatment of **primary axillary** (i.e., underarm) **hyperhidrosis** in patients ≥ 9 years of age.¹ Qbrexza is applied topically using a single cloth once every 24 hours to clean dry skin on both of the underarm areas only; it is not for use on other body areas.

Guidelines

There are currently no guidelines for the treatment of hyperhidrosis published by a professional society. However, the International Hyperhidrosis Society, an independent, non-profit organization, provides an algorithm for the treatment of axillary hyperhidrosis (updated 2018).² Topical antiperspirant therapy or Qbrexza are both listed as initial treatment choices. It is noted in the algorithm that typically aluminum chloride hexahydrate 20% topical solution is the most commonly prescribed agent.

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Qbrexza. All approvals are provided for the duration noted below.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Qbrexza is recommended in those who meet the following criteria:

FDA-Approved Indication

1. **Hyperhidrosis, Primary Axillary.** Approve for 1 year if the patient meets ALL of the following (A, B, C, and D):
 1. Patient is ≥ 9 years of age; AND
 1. Hyperhidrosis is significantly interfering with the ability to perform age-appropriate activities of daily living; AND
 1. The prescriber has excluded secondary causes of hyperhidrosis; AND
 1. Patient meets ONE of the following (i or ii):
 1. Patient has tried one prescription aluminum chloride-containing topical antiperspirant for at least 4 weeks and experienced inadequate efficacy; OR
Note: Examples of prescription aluminum chloride-containing topical antiperspirants include Xerac AC (aluminum chloride 6.25% topical solution), Drysol (aluminum chloride 20% topical solution).
 1. According to the prescriber, the patient has experienced significant intolerance with an aluminum-containing topical antiperspirant.

05/01/2024

© 2024. All Rights Reserved.

This document is confidential and proprietary. Unauthorized use and distribution are prohibited.

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Qbrexza is not recommended in the following situations:

- 54. **Hyperhidrosis, other than Primary Axillary.** Qbrexza is not intended for application to areas other than the axillae.¹
- 55. **Concurrent Use with Sofdra (sofpironium 12.45% topical gel).** The safety and efficacy of concurrent use of Qbrexza and Sofdra have not been established.
- 56. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hyperlipidemia – Nexletol Prior Authorization Policy

- Nexletol® (bempedoic acid tablets – Esperion)

REVIEW DATE: 05/08/2024

OVERVIEW

Nexletol, an adenosine triphosphate-citrate lyase inhibitor, is indicated for the following uses:¹

- To reduce the risk of myocardial infarction (MI) and coronary revascularization in adults who are unable to take recommended statin therapy (including those not taking a statin) with either: 1) **established cardiovascular disease (CVD)**, or 2) **at high risk for a CVD event but without established CVD**.
- **Primary hyperlipidemia**, including **heterozygous familial hypercholesterolemia (HeFH)**, in adults as an adjunct to diet, in combination with other low-density lipoprotein cholesterol (LDL-C) lowering therapies, or alone when concomitant LDL-C lowering therapy is not possible, to reduce LDL-C.

The safety and effectiveness have not been established in pediatric patients.¹

Clinical Efficacy

CLEAR Outcomes was a randomized, double-blind, placebo-controlled trial involving 13,970 adults, 18 to 85 years of age who were unable or unwilling to take statins due to unacceptable adverse events. Patients had or were at high risk for CVD.^{1,2} Patients without established CVD were considered high risk for CVD based on meeting at least one of the following: diabetes mellitus (type 1 or type 2) in females > 65 years of age or males > 60 years of age; a Reynolds Risk score > 30% or a SCORE Risk score > 7.5% over 10 years; or a coronary artery calcium score > 400 Agatston units at any time in the past.¹ Patients were assigned to receive Nexletol or placebo.^{1,2} Use of statins at very low doses were permitted, as well as other lipid lowering therapies (e.g., ezetimibe, bile acid sequestrants, fibrates). The mean patient age was 65 years. In total, 70% of patients had a previous cardiovascular (CV) event (secondary prevention population) whereas 30% of patients were categorized as being in the primary prevention group. In total, 38% of patients were receiving at least one lipid-modifying therapy. At baseline, 23% of patients were utilizing a statin and 12% of patients were on ezetimibe. The mean LDL-C at baseline was 139 mg/dL. The median follow-up was 40.6 months. The mean LDL-C level after 6 months of treatment with Nexletol was 107 mg/dL vs. 136 mg/dL for placebo. The primary endpoint (death from CV causes, nonfatal MI, nonfatal stroke, or coronary revascularization) occurred in 11.7% of patients in the Nexletol group vs. 13.3% of patients in the placebo group (P = 0.004). The composite endpoint (death from CV causes, nonfatal stroke, or nonfatal MI) occurred in 8.2% of patients given Nexletol vs. 9.5% of patients in the placebo group (P = 0.006).

Guidelines

Many guidelines are available regarding the treatment of patients with dyslipidemia.³⁻¹¹ For patients with elevated LDL-C, statins are the cornerstone of therapy and recommended first-line to be used at maximally tolerated doses due to the established benefits regarding the reduction of CV risks. Atorvastatin 40 mg to 80 mg once daily (QD) and rosuvastatin 20 mg to 40 mg QD are considered high-intensity statins as they achieve LDL-C lowering of ≥ 50%.

- The **American College of Cardiology (ACC) Expert Consensus Decision Pathway on the Role of Non-Statin Therapies** for LDL-Cholesterol Lowering in the Management of Atherosclerotic

Cardiovascular Disease (ASCVD) Risk (2022) make several recommendations.³ For adults with clinical ASCVD at very high risk (e.g., patients with major ASCVD events, HeFH, diabetes) who are on statin therapy for secondary prevention, the general goal is $\geq 50\%$ LDL-C reduction and an LDL-C < 55 mg/dL (or non-high-density lipoprotein cholesterol [HDL-C] < 85 mg/dL) with maximally tolerated statin therapy. If the above goals are not achieved, the initial non-statin agents recommended include ezetimibe and/or a proprotein convertase subtilisin kexin type 9 (PCSK9) monoclonal antibody (i.e., Repatha® [evolocumab subcutaneous injection] or Praluent® [alirocumab subcutaneous injection]). Nexletol can be considered after these therapies.

- The **American Heart Association (AHA)/ACC** guidelines on the management of blood cholesterol (2018) define patients with ACSVD as those with acute coronary syndrome, those with a history of MI, stable or unstable angina or coronary or other revascularizations, stroke, transient ischemic attack, or peripheral arterial disease.^{4,5} An LDL-C < 70 mg/dL is recommended for most patients with ASCVD to reduce CV risk. Guidelines and reviews have recognized that patients with an elevated coronary artery calcium or calcification score (e.g., ≥ 300 Agatston units) are at an increased risk of CV events.¹³⁻¹⁶
- The **American Diabetes Association Standards of Care for Diabetes** discuss CV disease and risk management (2024).⁸ For patients with diabetes who are 40 to 75 years of age at higher CV risk (including those with one or more ASCVD risk factors), it is recommended to use high-intensity statin therapy to reduce LDL-C by $\geq 50\%$ of baseline and to target an LDL-C of < 70 mg/dL. Also, for patients with diabetes who are 40 to 75 years of age at higher CV risk, especially those with multiple ASCVD risk factors and an LDL-C ≥ 70 mg/dL, it may be reasonable to add ezetimibe or a PCSK9 inhibitor to a maximum tolerated statin. In patients with diabetes intolerant to statin therapy, treatment with Nexletol is recommended to reduce CV event rates as an alternative cholesterol-lowering plan.
- Guidelines for **Chronic Coronary Disease from the AHA and ACC** (along with other organizations) [2023] state in such patients who are judged to be at very high risk and on maximally tolerated statin therapy and with an LDL-C ≥ 70 mg/dL, ezetimibe can be beneficial to further reduce the risk of a major adverse coronary event.⁹ Patients with chronic coronary disease who are considered to be at very high risk who have an LDL-C ≥ 70 mg/dL who are receiving maximally tolerated statins and ezetimibe, a PCSK9 monoclonal antibody can be beneficial to further reduce the risk of a major adverse coronary event. In patients with chronic coronary disease who are on maximally tolerated statin therapy who have an LDL-C ≥ 70 mg/dL and in whom ezetimibe and a PCSK9 monoclonal antibody are not adequate or are not tolerated, it may be reasonable to add Nexletol.
- The **American Association of Clinical Endocrinologists and American College of Endocrinology** has guidelines regarding the management of dyslipidemia and the prevention of CV disease (2020).⁷ Nexletol is cited as an option for intensification of therapy after use of standard agents such as high-intensity/moderate-intensity statins.
- The **International Lipid Expert Panel** published a position paper in 2023 on use of Nexletol in the management of lipid disorders and CV risk.¹⁰ One recommendation is that in patients with statin intolerance, Nexletol monotherapy, or in combination with ezetimibe and other non-statin drugs is recommended to enable patients to achieve therapeutic goals. In primary prevention, Nexletol may be considered for patients at high and very high CV risk who, despite optimally maximally tolerated doses of statins and ezetimibe are not achieving target LDL-C levels.
- **The AHA** published a scientific statement regarding familial hypercholesterolemia (2015).¹¹ Key points are that the condition may start early (in childhood or adolescence) and is noted by LDL-C levels ≥ 190 mg/dL. Premature CV disease can result. Diagnosis can be confirmed by genetic testing. The Dutch Lipid Clinic Network criteria and Simon Broome criteria may also be used which incorporate cholesterol levels, family history, clinical findings, and physical manifestations.

Aggressive lipid-lowering therapy is recommended to achieve LDL-C reductions of at least 50%.¹¹ Other information also provides guidance on the diagnosis of HeFH.¹²

POLICY STATEMENT

Prior Authorization is recommended for prescription benefit coverage of Nexletol. All approvals are provided for the duration noted below. A patient who has previously met Initial Therapy criteria for Nexletol for the requested indication under the Coverage Review Department and is currently receiving Nexletol is only required to meet continuation of therapy criteria (i.e., currently receiving therapy). If past criteria have not been met under the Coverage Review Department and the patient is currently receiving Nexletol, or is restarting Nexletol, Initial Therapy criteria must be met.

Automation: None.

RECOMMENDED AUTHORIZATION CRITERIA

Coverage of Nexletol is recommended in those who meet the following criteria:

FDA-Approved Indications

67. Established Cardiovascular Disease.* Approve for 1 year if the patient meets ONE of the following (A or B):

A) Initial Therapy. Approve if the patient meets ALL of the following (i, ii, and iii):

- i.** Patient is ≥ 18 years of age; AND
- ii.** Patient has had ONE of the following conditions or diagnoses (a, b, c, d, e, or f):
 - a)** A previous myocardial infarction or a history of an acute coronary syndrome; OR
 - b)** Angina (stable or unstable); OR
 - c)** A past of stroke or transient ischemic attack; OR
 - d)** Coronary artery disease; OR
 - e)** Peripheral arterial disease; OR
 - f)** Patient has undergone a coronary or other arterial revascularization procedure in the past; AND

Note: Examples include coronary artery bypass graft surgery, percutaneous coronary intervention, angioplasty, and coronary stent procedures.

iii. Patient meets ONE of the following (a or b):

- a)** Patient meets ALL of the following [(1), (2), and (3)]:
 - (1)** Patient has tried one high-intensity statin therapy (i.e., atorvastatin ≥ 40 mg daily; rosuvastatin ≥ 20 mg daily [as a single entity or as a combination product]); AND
 - (2)** Patient has tried one high-intensity statin above along with ezetimibe (as a single-entity or as a combination product) for ≥ 8 continuous weeks; AND
 - (3)** Low-density lipoprotein cholesterol level after this treatment regimen remains ≥ 55 mg/dL; OR
- b)** Patient has been determined to be statin intolerant by meeting ONE of the following [(1) or (2)]:
 - (1)** Patient experienced statin-related rhabdomyolysis; OR

Note: Rhabdomyolysis is statin-induced muscle breakdown that is associated with markedly elevated creatine kinase levels (at least 10 times the upper limit of normal), along with evidence of end organ damage, which can include signs of acute renal injury (noted by substantial increases in serum creatinine [Scr] levels [$a \geq 0.5$ mg/dL increase in Scr or doubling of the Scr] and/or myoglobinuria [myoglobin present in urine]); OR

(2) Patient meets ALL of the following [(a), (b), and (c)]:

(a) Patient experienced skeletal-related muscle symptoms; AND

Note: Examples of skeletal-related muscle symptoms include myopathy (muscle weakness) or myalgia (muscle aches, soreness, stiffness, or tenderness).

(b) The skeletal-muscle related symptoms occurred while receiving separate trials of both atorvastatin and rosuvastatin (as single-entity or combination products); AND

(c) When receiving separate trials of both atorvastatin and rosuvastatin (as single-entity or as combination products), the skeletal-related muscle symptoms resolved upon discontinuation of each respective statin therapy (atorvastatin and rosuvastatin); OR

Note: Examples of skeletal-related muscle symptoms include myopathy and myalgia.

B) Patient Currently Receiving Nexletol. Approve if according to the prescriber, the patient has experienced a response to therapy.

Note: Examples of a response to therapy include decreasing low-density lipoprotein cholesterol (LDL-C), total cholesterol, non-high-density lipoprotein (non-HDL-C), or apolipoprotein B levels. Also, if the patient is currently receiving the requested therapy but has not previously received approval of Nexletol for this specific indication through the Coverage Review Department, review under criteria for Initial Therapy. If the patient is restarting therapy with Nexletol, Initial Therapy criteria must be met.

53. Heterozygous Familial Hypercholesterolemia (HeFH).* Approve for 1 year if the patient meets ONE of the following (A or B):

A) Initial Therapy. Approve if the patient meets ALL of the following (i, ii, and iii):

i. Patient is ≥ 18 years of age; AND

ii. Patient meets ONE of the following (a, b, or c):

a) Patient has an untreated low-density lipoprotein cholesterol (LDL-C) level ≥ 190 mg/dL (prior to treatment with antihyperlipidemic agents); OR

b) Patient has phenotypic confirmation of heterozygous familial hypercholesterolemia; OR

Note: Examples include pathogenic variants at the low-density lipoprotein receptor (LDLR), apolipoprotein B (apo B), proprotein convertase subtilisin kexin type 9 (PCSK9), or low-density lipoprotein receptor adaptor protein 1 (LDLRAP1) gene.

c) Patient has been diagnosed with heterozygous familial hypercholesterolemia meeting ONE of the following diagnostic criteria thresholds [(1) or (2)]:

(1) Prescriber confirms that the Dutch Lipid Network criteria score was > 5 ; OR

(2) Prescriber confirms that Simon Broome criteria met the threshold for “definite” or “possible (or probable)” familial hypercholesterolemia; AND

iii. Patient meets ONE of the following (a or b):

a) Patient meets ALL of the following [(1), (2), and (3)]:

(1) Patient has tried one high-intensity statin therapy (i.e., atorvastatin ≥ 40 mg daily; rosuvastatin ≥ 20 mg daily [as a single-entity or as a combination product]); AND

(2) Patient has tried one high-intensity statin above along with ezetimibe (as a single-entity or as a combination product) for ≥ 8 continuous weeks; AND

(3) Low-density lipoprotein cholesterol level after this treatment regimen remains ≥ 70 mg/dL; OR

b) Patient has been determined to be statin intolerant by meeting ONE of the following [(1) or (2)]:

(1) Patient experienced statin-related rhabdomyolysis; OR

Note: Rhabdomyolysis is statin-induced muscle breakdown that is associated with markedly elevated creatine kinase levels (at least 10 times the upper limit of normal),

along with evidence of end organ damage which can include signs of acute renal injury (noted by substantial increases in serum creatinine [Scr] levels [$a \geq 0.5$ mg/dL increase in Scr or doubling of the Scr] and/or myoglobinuria [myoglobin present in urine]); OR

(2) Patient meets ALL of the following [(a), (b), and (c)]:

(a) Patient experienced skeletal-related muscle symptoms; AND

Note: Examples of skeletal-related muscle symptoms include myopathy (muscle weakness) or myalgia (muscle aches, soreness, stiffness, or tenderness).

(b) The skeletal-muscle related symptoms occurred while receiving separate trials of both atorvastatin and rosuvastatin (as single-entity or combination products); AND

(c) When receiving separate trials of both atorvastatin and rosuvastatin (as single-entity or as combination products), the skeletal-related muscle symptoms resolved upon discontinuation of each respective statin therapy (atorvastatin and rosuvastatin); OR

Note: Examples of skeletal-related muscle symptoms include myopathy and myalgia.

B) Patient Currently Receiving Nexletol. Approve if according to the prescriber, the patient has experienced a response to therapy.

Note: Examples of a response to therapy include decreasing low-density lipoprotein cholesterol (LDL-C), total cholesterol, non-high-density lipoprotein (non-HDL-C), or apolipoprotein B levels. Also, if the patient is currently receiving the requested therapy but has not previously received approval of Nexletol for this specific indication through the Coverage Review Department, review under criteria for Initial Therapy. If the patient is restarting therapy with Nexletol, Initial Therapy criteria must be met.

54. Primary Hyperlipidemia.* Approve for 1 year if the patient meets ONE of the following (A or B):

Note: This is not associated with established cardiovascular disease or heterozygous familial hypercholesterolemia (HeFH) and may be referred to as combined hyperlipidemia, hypercholesterolemia (pure, primary), dyslipidemia, or increased/elevated low-density lipoprotein cholesterol (LDL-C) levels.

A) Initial Therapy. Approve if the patient meets ALL of the following (i, ii, and iii):

i. Patient is ≥ 18 years of age; AND

ii. Patient meets ONE of the following (a or b):

a) Patient has a coronary artery calcium or calcification score ≥ 300 Agatston units;
OR

b) Patient has diabetes; AND

iii. Patient meets ONE of the following (a or b):

a) Patient meets ALL of the following [(1), (2), and (3)]:

(1) Patient has tried one high-intensity statin therapy (i.e., atorvastatin ≥ 40 mg daily; rosuvastatin ≥ 20 mg daily [as a single-entity or as a combination product]); AND

(2) Patient has tried the one high-intensity statin therapy above along with ezetimibe (as a single-entity or as a combination product) for ≥ 8 continuous weeks; AND

(3) LDL-C level after this treatment regimen remains ≥ 70 mg/dL; OR

b) Patient has been determined to be statin intolerant by meeting ONE of the following [(1) or (2)]:

(1) Patient experienced statin-related rhabdomyolysis; OR

Note: Rhabdomyolysis is statin-induced muscle breakdown that is associated with markedly elevated creatine kinase levels (at least 10 times the upper limit of normal), along with evidence of end organ damage which can include signs of acute renal injury (noted by substantial increases in serum creatinine [Scr] levels [$a \geq 0.5$ mg/dL increase in Scr or doubling of the Scr] and/or myoglobinuria [myoglobin present in urine]).

(2) Patient meets ALL of the following [(a), (b), and (c)]:

(a) Patient experienced skeletal-related muscle symptoms; AND

Note: Examples of skeletal-related muscle symptoms include myopathy (muscle weakness) or myalgia (muscle aches, soreness, stiffness, or tenderness).

(b) The skeletal-muscle related symptoms occurred while receiving separate trials of both atorvastatin and rosuvastatin (as single-entity or combination products); AND

(c) When receiving separate trials of both atorvastatin and rosuvastatin (as single-entity or as combination products), the skeletal-related muscle symptoms resolved upon discontinuation of each respective statin therapy (atorvastatin and rosuvastatin); OR

Note: Examples of skeletal-related muscle symptoms include myopathy and myalgia.

B) Patient Currently Receiving Nexletol. According to the prescriber, the patient has experienced a response to therapy.

Note: Examples of a response to therapy include decreasing low-density lipoprotein cholesterol (LDL-C), total cholesterol, non-high-density lipoprotein (non-HDL-C), or apolipoprotein B levels. Also, if the patient is currently receiving the requested therapy but has not previously received approval of Nexletol for this specific indication through the Coverage Review Department, review under criteria for Initial Therapy. If the patient is restarting therapy with Nexletol, Initial Therapy criteria must be met.

Note:

* A patient may have a diagnosis that pertains to more than one indication, therefore, consider review under different approval conditions, if applicable (e.g., a patient with heterozygous familial hypercholesterolemia may have established cardiovascular disease, a patient with primary hyperlipidemia may have heterozygous familial hypercholesterolemia).

CONDITIONS NOT RECOMMENDED FOR APPROVAL

Coverage of Nexletol is not recommended in the following situations:

191. Coverage is not recommended for circumstances not listed in the Recommended Authorization Criteria. Criteria will be updated as new published data are available.

PRIOR AUTHORIZATION POLICY

POLICY: Hyperlipidemia – Nexlizet Prior Authorization Policy

- Nexlizet® (bempedoic acid and ezetimibe tablets – Esperion)

REVIEW DATE: 05/08/2024

OVERVIEW

Nexlizet contains bempedoic acid, an adenosine triphosphate-citrate lyase inhibitor, and ezetimibe, a cholesterol absorption inhibitor. It is indicated for the following:¹

- **Primary hyperlipidemia**, including **heterozygous familial hypercholesterolemia (HeFH)**, in adults as an adjunct to diet, alone or in combination with other low-density lipoprotein cholesterol (LDL-C) lowering therapies, to reduce LDL-C.

The bempedoic acid component of Nexlizet (known as Nexletol® [bempedoic acid tablets]) is indicated for the following:¹

- To reduce the risk of myocardial infarction (MI) and coronary revascularization in adults who are unable to take recommended statin therapy (including those not taking a statin) with either 1) **established cardiovascular disease (CVD)** or 2) **at high risk for a CVD event but without established CVD**.

The safety and effectiveness have not been established in pediatric patients.¹

Clinical Efficacy

CLEAR Outcomes was a randomized, double-blind, placebo-controlled trial involving 13,970 adults, 18 to 85 years of age who were unable or unwilling to take statins due to unacceptable adverse events. Patients had or were at high risk for cardiovascular disease (CVD).^{1,2} Patients without established CVD were considered high risk for CVD based on meeting at least one of the following: diabetes mellitus (type 1 or type 2) in females > 65 years of age or males > 60 years of age; a Reynolds Risk score > 30% or a SCORE Risk score > 7.5% over 10 years; or a coronary artery calcium score > 400 Agatston units at any time in the past.¹ Patients were assigned to receive Nexletol or placebo.^{1,2} Use of statins at very low doses were permitted, as well as other lipid-lowering therapies (e.g., ezetimibe, bile acid sequestrants, fibrates). The mean patient age was 65 years. In total, 70% of patients had a previous cardiovascular (CV) event (secondary prevention population) whereas 30% of patients were categorized as being in the primary prevention group. In total, 38% of patients were receiving at least one lipid-modifying therapy. At baseline, 23% of patients were utilizing a statin and 12% of patients were on ezetimibe. The mean LDL-C at baseline was 139 mg/dL. The median follow-up was 40.6 months. The mean LDL-C level after 6 months of treatment with Nexletol was 107 mg/dL vs. 136 mg/dL for placebo. The primary endpoint (death from CV causes, nonfatal myocardial infarction [MI], nonfatal stroke, or coronary revascularization) occurred in 11.7% of patients in the Nexletol group vs. 13.3% of patients in the placebo group (P = 0.004). The composite endpoint (death from CV causes, nonfatal stroke, or nonfatal MI) occurred in 8.2% of patients given Nexletol vs. 9.5% of patients in the placebo group (P = 0.006).

Guidelines
